1 Introduction

1.1 Purpose

This document forms part of the package of documents describing the Data Flow System for VISTA, the Visible and Infrared Telescope for Astronomy. As stated in [AD1] "The Calibration Plan is the prime document which describes the different instrument-specific components of the Data Flow System".

1.2 Scope

This document describes the VISTA DFS calibration plan for the output from the 16 Raytheon VIRGO IR detectors in the (Infra Red) camera for VISTA. The baseline requirements for calibration are included in the VISTA DFS Impact Document [AD2]. The major reduction recipes and algorithms to be applied to the data are described in the VISTA DFS Data Reduction Library Design [RD1].

Each camera exposure will produce a 'pawprint' consisting of 16 non-contiguous images of the sky, one from each detector. The VISTA pipeline will remove instrumental artefacts, combine the pawprint component exposures offset by small jitters, and photometrically and astrometrically calibrate each pawprint. It will also provide Quality Control measures. It will not combine multiple adjacent pawprints into contiguous filled images, nor stack multiple pawprints at the same sky position.

This document does not describe any calibrations or procedures relating to the CCD detectors that are also located within the camera and which interact with the Telescope Control System.

This document covers only the Routine Phase of operations of VISTA's IR Camera. In particular it does not describe any calibrations or procedures that form part of the Commissioning Plan for VISTA, nor any procedures needed during routine Engineering Maintenance. [Except for HOWFS observations, which are made using the science detectors, and passed to the science archive.] Arrangements for processing any calibrations or procedures carried out under such categories are the responsibility of the VISTA Project Office.

1.3 Applicable Documents

1.6 Glossary

Confidence Map	An integer array, normalized to a median of 100% which is					
_	associated with an image. Combined with an estimate of the					
	sky background variance of the image it assigns a relative					
	weight to each pixel in the image and automatically factors in					
	an exposure map. Bad pixels are assigned a value of 0, 100%					
	has the value 100, and the maximum possible is 32767					
	(negative values are reserved for future upgrades). The					
	background variance value is stored in the FITS header. It is					
	especially important in image filtering, mosaicing and					
	stacking.					
ЫТ	Digital Integration Time, Separate readouts are summed					

- **DIT** Digital Integration Time. Separate readouts are summed digitally.
- **Exposure** The stored product of many individual **integrations** that have been co-added in the DAS. Each exposure is associated with an exposure time.

Integration A simple snapshot, within the DAS, of a specified elapsed time **DIT** seconds. This elapsed time is known as the integration time.

Jitter (pattern) A pattern of **exposures** at positions each shifted by a small **movement** (<30 arcsec) from the reference position. Unlike a **microstep** the non-integral part of the shifts is any fractional number of pixels. Each position of a jitter pattern can contain a **microstep** pattern.

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	10 of 72

- **Mesostep** A sequence of **exposures** designed to completely sample across the face of the detectors in medium-sized steps to monitor residual systematics in the photometry.
- Microstep (pattern) A pattern of exposures at positions each shifted by a very small movement (<3 arcsec) from the reference position. Unlike a jitter the non-integral part of the shifts are specified as 0.5 of a pixel, which allows the pixels in the series to be interleaved in an effort to increase sampling. A microstep pattern can be contained within each position of a jitter pattern.
 - **Movement** A change of position of the telescope that is not large enough to require a new guide star.
 - **Offset** A change of position of the telescope that is not large enough to require a telescope **preset**, but is large enough to require a new guide star.
 - **Pawprint** The 16 non-contiguous images of the sky produced by the VISTA IR camera, with its 16 non-contiguous chips (see Figure 2-2). The name is from the similarity to the prints made by the padded paw of an animal (the analogy suits earlier 4-chip cameras better).
 - **Preset** A telescope slew to a new position involving a reconfiguration of the telescope control system and extra housekeeping operations that are not necessary for a **movement** or an **offset**.
 - **Tile** A filled area of sky fully sampled (filling in the gaps in a pawprint) by combining multiple **pawprints**. Because of the detector spacing the minimum number of pointed observations (with fixed offsets) required for reasonably uniform coverage is 6, which would expose each piece of sky, away from the edges of the tile, to at least 2 camera pixels. The pipeline does not combine **pawprints** into tiles.

2 Overview

2.1 Hardware

VISTA is a wide field alt-az telescope designed for a single purpose, surveys, and which does not have a conventional focus. It can only be used with a purpose built camera, and is delivered with an IR camera. Thus it is the performance and pointing of the telescope-camera system that is important.

The telescope by itself has no capability to lock onto a guide star or carry out wave front sensing. The IR Camera therefore contains, as well as 16 IR detectors, two Autoguider CCDs and two low order wave front sensor (LOWFS) units, each with two CCDs, operating in the I band, as shown in Fig 2-1. Two autoguiders, on opposite

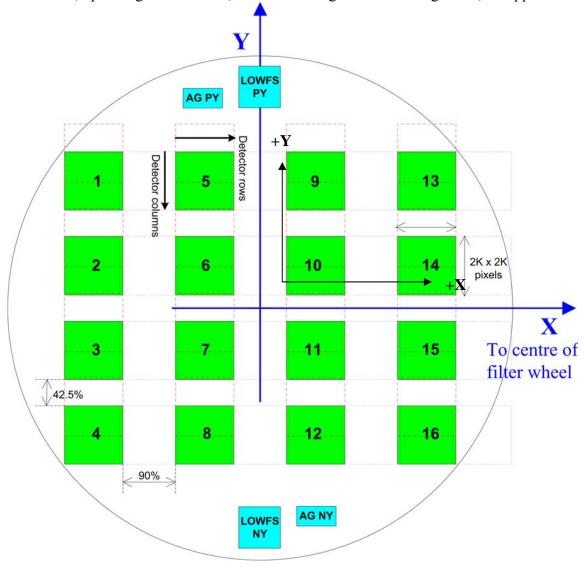

Figure 2-1 VISTA Focal plane: Each of the 4 groups of detectors in the Y direction (e.g. #s 1-4, 5-8, 9-12, 13-16) is read out by a separate IRACE controller.

SYSTEM	Plan	Page:	12 of 72

edges of the focal plane, are used in order to meet the sky coverage requirements, although only one is allowed to apply corrections to the telescope axes at any given time. The LOWFSs measure aberrations that are used by the external active optics control process to adjust the position of the 5 axis (x, y, z, tip, tilt) secondary mirror support system and some aspects of the M1 surface to maintain image quality. The LOWFS operates roughly every 1 minute during tracking and needs exposures of ~40 sec to average out seeing effects. Although the Autoguiders and LOWFSs are physically located within the IR camera, both are considered part of the TCS from a software point of view. This is primarily to maintain consistency with existing VLT software and standards. The VISTA pipeline receives no data from these CCDs. The

CCDs therefore do not impact on the VISTA pipeline, except in so far as the pointing and image quality of the camera are dependent on their proper operation.

A high order wave front (curvature) sensor (HOWFS) uses some of the science detectors to determine occasional adjustments to the primary mirror support system. (This is done perhaps once at the start of the night and once around midnight.) Processing the signals from the HOWFS is done within the Instrument Workstation, and so the pipeline will not have to deal with the HOWFS at all. However all data from the IR detectors, including HOWFS data, is passed to the science archive, so the necessary calibration templates for the HOWFS are covered here.

Within the IR Camera are 16 Raytheon 2048x2048 VIRGO detectors arranged in a sparse array. Each camera exposure produces a pawprint consisting of 16 non-contiguous images of the sky. An example display of a complete FITS file consisting of a VISTA "pawprint" is shown in Figure 2-2.

The VISTA IR camera has only one moving part, the filter wheel which has 8 filter holders, each filter holder containing 16 filters, one for each IR detector. There are further auxiliary (beam splitting) filters for use with the high order wave front sensor.

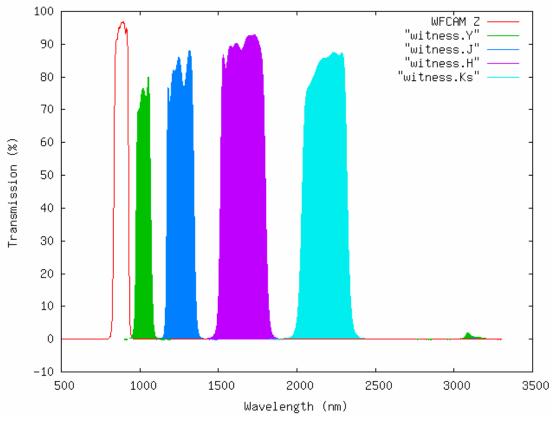

Figure 2-3 Filter Transmission Curves for Reference Samples of Y, J, H, and K_s bands.

One of the filter holders contains a set of 16 cold blanks (metal units which completely block the detectors from incoming sky radiation, and produce negligible thermal emission) which are used for taking dark frames. The instrument will be delivered with 6 filter sets (Z, Y, J, H, K_s and a narrow-band at 1.185μ - Figure 2-3)

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	14 of 72

and a further set of cold blanks, which can be replaced with other filters in due course. The position angle of the camera axis can be controlled by the instrument rotator. Single integrations are taken by a Reset-Read-Read procedure with the difference of the two Reads being performed within the DAS.

2.2 Observing Modes

IMAGING is the only mode in which science data will be acquired, but the science array is used to acquire data for internal wave-front analysis.

2.2.1 Imaging Mode Description

The sky target position is acquired and tracked and in parallel (for observing efficiency) the required filter set is placed in the beam. The LOWFS provides the necessary updates to the M2 and M1 support units. A set of exposures, each of which may consist of a number of integrations, are taken and are usually jittered by small offsets, to remove bad pixels and determine sky background. The set of exposures produced is combined in the pipeline to create a single pawprint, in which the jitters from all detectors are included.

Six such pawprints, taken at appropriate offsets, can be combined to produce an almost uniformly sampled image of a contiguous region, each bit of sky, except at the edges, having been observed by at least two pixels. The individual exposures making up each pawprint may be made on a jitter or a microstep pattern. Microstep patterns are interleaved rather than combined, so the calibration procedures are unchanged, though the data volume increases.

2.2.2 Calibrations

The calibrations are of four sorts:

- i. those that characterize the properties of the transfer function (image in, electrons out) of the end-to-end system (telescope, camera, IR detector system including associated controllers, etc.) so that instrumental effects can be removed from the data. As VISTA has a wide field of view, particular attention must be paid to variations across the field;
- ii. those that characterize the astrometric distortions of the images;
- iii. those that characterize the photometric zero points and extinction coefficients corresponding to the images;
- iv. those that generate Quality-Control measures.

2.2.3 High Order Wave Front Sensor (HOWFS) Mode

The HOWFS mode is processed in the Instrument Workstation and is logically part of the TCS. However, as it uses the IR detectors, all of whose data are passed to the archive, it is considered as a separate observing mode for VISTA pipeline purposes.

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	15 of 72

In HOWFS mode a special beam-splitting filter is used to make a curvature sensor in which two images (above and below focus) of a reference star are formed and used to generate corrections to the forces in the M1 support unit, ensuring the mirror figure is maintained. This mode will typically be used of order twice a night (start and around midnight), or less often if the repeatability of the lookup table is good.

2.2.4 Calibrations

The HOWFS uses some of the science mode IR detectors, but has a special beam splitting filter whose unique signature needs to be removed from the HOWFS data before it can be analysed. However, this flat-fielding is carried out within the HOWFS image-analysis software (which is part of the Camera Software) and not by the pipeline, and is noted here for completeness.

2.3 Pipeline

The VISTA pipeline will produce photometrically and astrometrically calibrated pawprints, with instrumental artefacts removed. In order to achieve almost uniform coverage of a full contiguous area of sky, a six point offset pattern is used by default. A template that implements this pattern is defined and the pipeline will calibrate the resulting six pawprints individually. The further step of combining these into a contiguous map is left to the science user.

For certain science programs the OS will allow distinct OBs for eventual "PI" processing; the main example of this would be observing offset sky frames to calibrate the sky in extended-object science frames. The QC pipeline is not required to associate such observations, but will perform routine reductions on such data.

Other processes which are not calibration issues, but which may nevertheless relate to achievable data quality, are not discussed here. Such (excluded) processes include:

- *co-addition of individual integrations* of a pawprint into a single exposure within the data-acquisition system;
- combination of many pawprints to cover contiguous areas of sky;
- *co-addition of many pawprints* to go deeper.

2.4 Operation

This section defines the observing modes, Section 3 contains an error discussion, Section 4 describes the calibration data required for instrumental signature removal, Section 5 describes the calibration data required for photometric calibration. Section 6 describes the calibration data to be derived from science data, including astrometric calibration. Section 7 discusses Quality Control measures based on regularly measured selected sets of calibrations for the purpose of instrument "health checks". Section 8 describes all templates and Section 9 the Technical Programs. Finally Section 10 details the Format of Data Frames.

The philosophy throughout is that the VISTA pipeline will be triggered by the completion of each template. In the case of a template aborting, the pipeline will process as far as possible with the available data. The content of the FITS headers

SYSTEM	Plan	Page:	16 of 72

allow the VISTA pipeline to handle the set of observed files as an ensemble and to choose appropriate processing based on the header information.

3 Calibration Accuracy

3.1 Overview

The error budgets for the astrometric, photometric and flat-fielding requirements have two generic components, systematic and random, that contribute to the overall errors.

We discuss each in turn and indicate how the requirements will be met by the strategy adopted.

3.2 Astrometric Error

The astrometric calibration will be based on the 2MASS PSC. 2MASS astrometry is derived from direct calibration to TYCHO 2 and is in the ICRS system. [Note that this requires RADECSYS = 'ICRS' in the FITS headers]. It is known to have average systematic errors better than ~100mas and RMS errors better than ~100mas, for all point sources with S:N > ~10:1 [AD2]. We will be using 2MASS as the primary astrometry calibrator and in tests on similar mosaic instruments we have shown that our suggested ZPN distortion model, combined with a linear plate solution for each detector, achieves astrometric calibration at the 100mas or better level.

The initial WCS will be based on the known detector characteristics (scale, orientation, focal plane position) and telescope pointing information (tangent point of optical axis on sky). The astrometric refinement algorithm will be based on a standard proven method we have developed for optical mosaic cameras and as such will be capable of automatically converging from starting points as far off as an arcmin. However, after commissioning updates we do not anticipate the initial WCS to be this inaccurate, since this level of accuracy is significantly larger than the combined error budget for the alignment of the various system components [RD4].

Further reduction in the internal astrometric systematics beyond 100mas may be possible by monitoring generic trends in the astrometric solution residuals, but this is out-with the scope of this document.

3.3 Photometric Error

The photometric calibration for VISTA will be measured in two ways:

- The initial photometric calibration for all filters will be based on the 2MASS PSC. The 2MASS photometric system is globally consistent to ~1% (Nikolaev et al. 2000). This approach will enable each detector image to be calibrated directly from the 2MASS stars that fall within the field of view. Experience with WFCAM indicates that this approach will result in a photometric calibration to better than 2% for VIRCAM.
- A network of standard star fields will be observed periodically throughout each night (approximately every 2 hours). These data will enable an independent calibration to be made on a nightly basis. These *touchstone* fields will provide important information on the stability of VIRCAM, and will be used to measure any intra-detector spatial systematics.

3.3.1 RMS

The error budget for photometry of astronomical sources requires photon noise to be the dominant noise source. For this to be the case, integration times should be chosen such that observations are general sky noise limited, i.e. sky noise should be much greater than RMS readout noise and dark current contributions. Clearly, this places a comparable requirement on the RMS contribution from flat fielding. However, providing the master flats used for this are combined from multiple observations with at least a total of 100,000 detected electrons this is easily achievable. In practice a goal of 0.1% RMS flat field noise due to photon noise contribution is the aim.

3.3.2 Additive systematics

More difficult problems to quantify are the systematics present in the various correction stages due to, for example, changing flat-field characteristics, reset anomalies, unexpected background variation and so on. The additive components of these systematics can be dealt with using a background tracking algorithm which effectively monitors and removes background variations to the level of 0.1% of sky, prior to performing object photometry. This will be part of the catalogue generation software. Subsequent derived object catalogues are therefore relatively insensitive to variations in any additive component provided such variations smoothly change over the image with typical scale length ~ 20 arcsec or greater. Abrupt jumps in background level within a single detector frame usually indicate either a processing problem (e.g. the sector non-linearity correction is incorrect) or a hardware problem.

Experience with other NIR mosaics (e.g. WFCAM) suggest that other additive systematic contributions such as fringing, will probably only occur at a relatively low level ($\sim 1\%$ of sky) and the current defringing scheme will reduce these to a level ($\sim 0.1\%$ of sky) where their impact is negligible.

The main unknown here is the stability of the reset anomaly. This will be characterised through laboratory tests during camera assembly and acceptance and further quantified during commissioning.

3.3.3 Multiplicative systematics

External differences between the detectors, the differential detector gains, will be calibrated from master twilight flat fields for each passband. In practice the main limitations here are those due to colour equation differences between the detectors, and to residual errors in the nonlinearity corrections rather than the properties of master flat field frames. Intra-detector systematics are taken care of by conventional flat fielding. However, both types of global multiplicative systematics typically can be controlled at the 1-2% level and can be externally monitored and further corrected by the "illumination" measurement correction stage described next. The final photometry correction stage is to use the illumination correction measurements to reduce the effects of uneven illumination e.g. scattered light in the flat fielding, residual detector differences and so on, to below the 2% level. This is a master calibration processing task that is probably best done as either a post main pipeline processing stage or at the science database extraction point.

	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	19 of 72

3.3.4 Extinction monitoring

The 2MASS-based calibration provides an instantaneous measurement of the throughput of the system, incorporating extinction. Even on cloudy nights, when the transmission is variable, this will provide a significantly better calibration than can be achieved with routine observations of standard star fields.

Offline, nightly trend analysis of the extinction derived from 2MASS, combined with regular observations of secondary photometric standard fields, set up in the VISTA instrumental system, will enable an independent calibration of most nights to the level of 1% to 2% global.

4 Calibration Data for Instrumental Signature Removal

4.1 Purpose

Section 4 describes what calibration data has to be collected with what frequency to allow one to remove instrumental signatures.

For each piece of calibration data required this section defines:

- **Responsible:** responsibility for obtaining the calibration data
- **Phase**: when the calibration data has to be acquired (day or night time)
- **Frequency**: how often calibration data need to be acquired.
- **Purpose:** reason for needing the calibration data
- **Procedure**: the procedure for acquiring the calibration data
- **Raw Outputs**: the output of the procedure
- **Prepared OBs/Templates**: the pre-prepared observation blocks or templates to acquire the calibration data
- **OT queue**: the corresponding Observing Tool queue for the Observation Blocks.
- **Pipeline Recipe**: The name (if any) of the processing recipe applied by the data flow system pipeline. Recipes may contain algorithms and procedures as subcomponents. Each such recipe corresponds to one listed in [RD1].
- **Pipeline Output**: the Pipeline output products, appended with (QC) for those also used as Quality Control parameters
- **Duration**: an estimate of the required time to execute the calibration procedure including overheads.
- **Prerequisites**: possible dependencies on instrumental or sky conditions or other calibration procedures are given
- See also: any further information.

The calibration data is used for instrumental signature removal. The aim is to provide pawprints as though taken with a perfect camera, which produces a photometrically linear, defect-free, evenly-illuminated, though sparsely sampled, reproduction of the sky. This will have no additional systematic, random noise or other artefacts, and will be on an arbitrary photometric and astrometric scale.

Off-sky calibrations and quality control measures will be made routinely, before and after observing, using the in-dome illuminated screen.

Operations

4.2 Reset Frames

Responsible:	Science (
Phase:	Daytime
Frequency:	Daily

Purpose: A Reset frame is a Reset-Read sequence with minimum exposure taken with the cold blank in (1 sec is the minimum VISTA can produce, but 10s would be a more realistic estimate for the duration for a single exposure including overheads as the IRACE system is specified to process an exposure within 5s and to allow the next exposure to start within 10s). It differs from a dark frame, which consists of a Reset-Read-Read sequence where the output is the difference of the two reads. The aim is to map the effect of the reset. Sequences of Reset frames will be taken offsky and analysed to estimate the stability of the reset pedestal and pixel to pixel variation.

Procedure: Read out frame, compare with library reset frame. FITS files Raw Outputs: Template: VIRCAM img cal reset.tsf OT queue: VIRCAM.Daytime.Calibration Pipeline Recipe: vircam reset combine Pipeline Outputs: Variance with respect to standard frame (QC) Duration: 10 s Prerequisites: See Also:

4.3 Dark Frames

Responsible:	Science Op	perations
r		

Phase: Daytime

Frequency: Daily

Purpose: Dark Frames are used to calibrate out and measure two separate additive effects.

- the accumulated counts that result from thermal noise (dark current). This is generally a small, but not negligible effect.
- an effect, here called 'reset anomaly', in which a significant residual structure is left in the image after the reset is removed in the DAS, when it does a correlated double sample (CDS, Reset-Read-Read).

Both dark current and reset anomaly are additive and can be removed together, using dark frames (exposures with cold blank filters completely blocking the detectors from incoming radiation) taken with the same integration time as the target observation. In order to minimize contamination from transient events, a dark frame would be a combination of many frames with rejection.

If the spatial structure of the reset anomaly is not stable with time

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	23 of 72

Procedure:	it could leave a challenging background variation over the detector, which may need to be removed with a background filter. This latter scenario is best avoided as real astronomical signal will inevitably be removed.(In general, for other instruments examined where the reset anomaly structure is repeatable and stable, the integration time seems to determine the spatial structure of the residuals, while the ambient flux seems to determine its intensity.)A series of dark frames will be taken with each integration and exposure time combination used for target observations so that
	the structure of the reset anomaly can be modelled correctly and
	the dark correction is consistent. The Dark template, which does not require the telescope, will insert the cold blank and perform a
	timed exposure. If the requested time is less than the array
	minimum read-out cycle time of \sim 1s (e.g. zero) the controller will deliver, and report, the minimum detector integration time of \sim 1s.

4.4 Dome flats

ŀ	Dome nat	5		
	Responsible:	Science Operations		
	Phase:	Daytime or non-observing nights.		
	Frequency:	Daily		
	Purpose:	Monitoring instrument performance, image structure, and confidence maps. They will not be used for gain correction (flat- fielding) due to non-uniform illumination over the whole of the focal plane and the different colour of the illumination compared to the night sky. Note that dome flats may have a spectral energy		
		distribution closer to that of some objects of interest and thus be more adequate for gain correction, but for pipeline processing whole fields in a consistent way an average gain/flat-field correction for typical objects is the usual method.		
	Procedure:	The Dome template will acquire the dome screen (constant illumination); a series of timed exposures are made through a given filter.		

- Raw Outputs:FITS filesPrepared OBs:VIRCAM_img_cal_domeflat.obx

Prerequisites:	The need for constant illumination of the dome screen implies that			
	the dome flats cannot be taken in conditions of variable or excessive			
	ambient light.			
See Also:	Dome flat observations are also employed in linearization			
	measurements described in 4.6 and in generating bad pixel maps.			

4.5 Detector Noise

Responsible: Science Operations

Phase: Daytime

Frequency: Daily

- Purpose: In order to understand the noise properties of the detectors, it is important to measure the readout noise and gain of each chip. This is a vital piece of information, not only as large changes in either property could signal a detector health issue, but also as further down the pipeline the issue of pixel rejection algorithms becomes important (for example, during jittering).
- Procedure: Both of these properties can be measured from a pair of dark exposure frames and a pair of dome flat frames. The dark exposures should have matching integration and exposure times to the dome flats, and both dome flat frames should be observed with the same dome illumination. Care should be taken to ensure that the flats are exposed in a region of the response curve where the detectors are reasonably linear.

	Bad pixel statistics (QC)		
Duration:	1		
Prerequisites:			
See Also:	Dome flat measures in 4.4		

4.7 Twilight Flats

Phase:	Twilight
	\mathcal{O}

Frequency: Evening/Morning

Purpose: Flat-fielding removes multiplicative instrumental signatures from the data. This includes pixel-to-pixel gain variations and the instrumental vignetting profile. It also provides a global gain correction between detectors and individual read out channels within each detector. (Each of the 16 detectors has 16 read out channels, giving a total of 256.)

Mean flat-fields also are the data source for the science-level confidence map for each detector and filter combination. This is similar to a weight/bad-pixel map where the mean level is normalized to a value of 100% and bad pixels are flagged with a value of zero. It is used in conjunction with an estimate of the sky background variance in each frame to propagate the weight of each individual pixel. Although this is especially important for later manipulation of the pawprints outside the VISTA pipeline for doing deep stacking and tiling, it is also vital for the object detection part of the pipeline which is used, *inter alia*, in astrometric and photometric corrections.

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	26 of 72

Mean flat-fields can be derived from a variety of sources (each with their own advantages and disadvantages). Sky flats taken at twilight have a good (but not perfect) colour match to the night sky observations we wish to correct, and can be taken under conditions where the contribution from night sky fringing, emission from dust (on the optical surfaces) and other spatial effects are most negligible. The slightly imperfect colour match between the twilight and night sky will cause a very small residual error in the gain correction. Dusk and dawn twilight flats can be combined (outside of the pipeline), to update the master flats, and thereby moderate effects caused by the significant variation in the illumination caused by the reset and read times.

Procedure: The sky level must be such that any emission from fringing or dust on the optical surface will be negligible in comparison, and this means that there is only a short time in which to acquire the twilight flats. It will not always be possible to get a complete set of twilight flats every night for schedules involving many filters or on nights with changeable weather. If, however, the detector flat-fields are sufficiently stable, then it is possible to use master flats taken over several nights, which is the method of choice.

OT queue: VIRCAM.Daytime.Calibration

Pipeline Recipe: vircam twilight combine

Pipeline Output:

t: Mean twilight flats Confidence maps

Change (vs calibDb) in mean gain correction coefficients between detectors and channels (QC)

10 min evening twilight, 10 min morning twilight.

Duration: Prerequisites: See Also:

4.8 Illumination Correction Measurement

Responsible: Science Operations Phase: Night

Frequency: Monthly

Purpose: The gain correction as modelled by the flat-field should remove all pixel-to-pixel gain differences as well as any large-scale variations due (generally) to vignetting within the focal plane. However, scattered light within the camera may lead to largescale background variations which cannot be modelled and removed, as its level depends critically on the ambient flux. Dividing a target frame by a flat-field frame that is affected by this will cause systematic errors in the photometry across the detector. It is necessary to map out the spatial systematic effects across each detector so that a correction map can be factored into

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	27 of 72

the final photometry measured from each detector.

Procedure: The illumination correction can be measured in two ways. In the event that observations of a secondary photometric standard field with a density of 100-200 objects per detector are available, then the illumination correction can be measured by looking at the spatial variation of the photometric zero-point across each detector. If such a field is not available, then a mesostep sequence is taken consisting of a series of exposures of a sparse field of relatively bright stars on a regular grid of offsets that cover one detector. Measuring a flux on each exposure allows the definition of a position-dependent scale factor (this must be done for each filter and each detector).

Raw Outputs:	FITS files
Prepared OBs:	VIRCAM_img_cal_illumination.obx
OT queue:	VIRCAM.Nighttime.Calibration
Pipeline Recipe:	vircam_mesostep_analyse
Pipeline Output:	Correction map
Duration:	30 min
Prerequisites:	Photometric conditions

5 Data for Photometric Calibration

5.1 Introduction

The camera will be on the telescope semi-permanently, in a survey mode, providing a stable configuration which enables a long-term approach to photometric calibration to be taken. The strategy is to define routine calibration procedures, so that the accuracy, and hence the scientific value, of the archive, will be maximized. Magnitudes will be calibrated on the Vega scale.

As briefly mentioned in Section 3.3, VIRCAM observations will enable two independent calibrations:

- 1. from the 2MASS all-sky point source catalogue and
- 2. from routine observations of standard star fields

We discus the details of the two methods below

5.2 Calibration from 2MASS

The photometric zeropoint is derived for each image from measurements of stars in the 2MASS point source catalogue (PSC) by solving

$$ZP_{VIRCAM} + m_{inst} - m_{2MASS} = CT(J - H)_{2MASS} + const$$

for all stars in common with VIRCAM (above a threshold signal-to-noise in the PSC and unsaturated in CIRCAM), where:

- ZP_{VIRCAM} is the zeropoint for the filter and detector
- m_{inst} is the VIRCAM instrumental magnitude for the filter (=-2.5log(counts/sec)
- m_{2MASS} is the 2MASS PSC magnitude
- *CT* is the colour term and is derived from a large number of observations
- $(J-H)_{2MASS}$ is the 2MASS PSC colour of the star
- *const* is an offset which may be required in some passbands to ensure the magnitude is on the Vega system.

Subsequent inter-detector comparisons will enable residual errors in the gain correction to be detected and calibrated. Offline analysis would provide a measure of the median zeropoint for the night, and an associated error (and scatter), indicative of photometric quality of the night.

5.3 Calibration from Standard Star Fields

At any time (t) on any night (n) for any star (i) in any filter waveband (b),

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	30 of 72

$$m^{cal}_{ib} = m^{inst}_{ibtn} + ZP_{btn} - \kappa_{btn}(X-1)$$
 Equation 1

where ZP is the Zero Point (i.e. the magnitude at airmass unity which gives 1 count/second at the detector), m^{cal} is the calibrated instrumental magnitude, m^{inst} is the measured instrumental magnitude (-2.5 × $log_{10}[counts/sec]$), κ is the extinction coefficient and X is the airmass of the observation. This assumes that the second-order extinction term and colour-dependency of κ are both negligible.

Typically, the Zero Point of the instrument + telescope system should be stable throughout the night. Long-term decreases in the sensitivity of the instrument, and hence a decreasing *ZP*, could be caused by for example the accumulation of dust on the primary mirror.

On photometric nights the extinction coefficient κ should be constant in each filter. The extinction κ will be monitored through each night assuming a fixed zero point and making measurements over a range of airmass. Although 2MASS found their extinction coefficients to vary seasonally any effect should be much less for VISTA since it has narrower filter profiles especially at J, and is at a much drier site.

A network of Secondary Standard photometric fields will be set up so that routine photometric standard observations can be made with the telescope in focus *every two hours*. The standard fields are selected to be 2MASS touchstone fields and or UKIRT faint standard fields, and many will have been observed and calibrated in advance by WFCAM. The secondary fields meet the following criteria:

- Extend over the area of the IR camera pawprint
- Span 24 hours in RA, with a target spacing of 2 hours.
- Enable observations over a range of airmass. Some must be chosen to pass close to the zenith of VISTA (for airmass unity). Some fields will be available to the North and South of the zenith to optimize telescope azimuth slewing. The remainder will be near-equatorial.
- Have a density of sources sufficient to characterize the systematic positiondependent photometric effects in VISTA, but not be too crowded. The target is of order 100 stars per detector with magnitudes no fainter than J=18, K_s=16 to avoid prohibitively long exposures.
- They should encompass as broad a spread as possible in colour in order to derive colour terms robustly and facilitate transformations from and to other filter systems and e.g. the AB magnitude system. i.e.

$$M^{std} = m_b^{cal} + C(M_x^{std} - M_y^{std})$$
 Equation 2

where M^{std} is the magnitude in a defined standard system, m_b^{cal} is the calibrated magnitude in the instrumental system, and *C* is the colour term for the appropriate standard colour index $(M_x^{std} - M_y^{std})$.

6 Calibration Data Derived from Science Data

6.1 For Instrument Signature Removal

6.1.1 Night-Sky Maps

n

Responsible: Science Operations Phase: Night

Frequency: Throughout night

Purpose: If experience shows that the detector flats are not reliably stable over the timescale of a night, then night-sky flats will have to be used instead. These are formed either from the target frames or from any special offset sky frames that might have been taken (for example where there is a large extended object in the field). All such frames over an appropriate time range are combined with rejection to form a normalized night sky flat-field. The advantage of dark flats over twilight flats is the better colour match to the average astronomical object. This minimises the sensitivity of the gain and flat-field correction to differential colour terms with respect to astronomical objects. However, fringing and thermal emission from dust particles on the optical surfaces can be high enough to affect the background significantly in some passbands. Dividing the target frames by a sky flat without correcting for these two additive effects could lead to significant systematic errors in photometry. In the Garching pipeline, master flats will be determined from as many observations as possible, but if it is determined that the flats vary rapidly, then only flats taken close in time may be useable.

Use normal science exposures.

Determine the characteristics of fringing and thermal emission
from dust on the optical surfaces during commissioning.
6.1.2

6.1.2 Sky Subtraction and Fringe Removal

Responsible:	Science operations
Phase:	Night
Frequency:	Throughout night
Purpose:	The sky background varies over large scales in the infrared. In
	some wavebands, fringing and thermal emission from any local
	dust (on optical surfaces) will also be present. All of these

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	33 of 72

effects can be removed using the sky-subtraction algorithm. The source of the sky background estimate is usually the science data frames themselves. In cases where large extended or very bright objects might be present, it may be necessary to use 'offset sky' exposures in the observation template.

Procedure: Preset or offset to, uncrowded, regions taken near or adjacent to the region of interest. Observe in the same way as the corresponding science field.

Pipeline Output:	Local sky estimate
	Fringe and dust maps
Duration:	Same as science field.
Prerequisites:	
See Also:	

6.1.3 Jittering

Responsible: Science Operations

Phase: Night

Frequency: Nearly all the time

- Purpose: Removal of bad pixels and other cosmetic effects, as well as cosmic rays, and determining the sky background. Typically a long exposure is split into several shorter exposures, which, rather than being repeated with each pixel looking at exactly the same sky position, are carried out at a series of different (jittered) positions. This is similar to microstepping (same template), but with less fine sampling, and the pipeline combines the jittered exposures using a rejection algorithm.
- Procedure: Perform a specified pattern of exposures at each position of a jitter pattern. Predefined patterns and movement size in pixels may be selected. Microsteps can be nested within each jitter position by setting the number of microsteps appropriately in the template.

Raw Outputs: **FITS Files** Template: VIRCAM img_obs_paw.tsf, VIRCAM img obs offsets.tsf OT queue: Science Pipeline Recipe: vircam jitter microstep process Pipeline Output: Combined frames of pawprint Confidence map for pawprint Duration: Variable Prerequisites: See Also: 6.1.4

VIRCAM img obs tile.tsf,

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	34 of 72

6.1.4 Microstepping

Responsible: Science operations

Phase: Night

Frequency: As required

- Purpose: Improved sampling. This is most likely to be employed in times of excellent seeing, when the point-spread function is undersampled. It can also be used if there are strong intra-pixel sensitivity (QE) variations. It may not be commonly used. It is similar to jittering (same template) but with improved sampling through finer pattern spacing, and the pipeline interleaves the exposures without further rejection.
- Procedure: Perform a specified pattern of exposures at each position of a microstep pattern. Predefined patterns and movement size in pixels may be selected, and there is a default pattern/size [2×2 pattern, modulo a 0.5 pixel shift]. By setting the number of microsteps appropriately in the template, microsteps can be nested within each jitter position.

6.2 For Astrometric Calibration

Astrometric calibration will take the instrument signature free pawprints and provide the transformation between pixel coordinates and celestial coordinates for each of the 16 constituent images, though still leaving the pawprints on an arbitrary photometric scale. The transformations are manifested in a Flexible-Image Transport System (FITS) [RD12] World-Coordinate System (WCS) [RD14]. The projection used will be Zenithal Polynomial (ZPN), based on the predicted properties from the optical design.

Quantifying the distortion terms used in the WCS will be done from on-sky observations. An initial astrometric distortion is available from the optical design, and an updated early empirical value will be derived from commissioning data. Following that, an increasingly accurate value will be derived from the astrometry of all target frames.

6.2.1 Optical Distortion Effects

Responsible:	Science Operations
Phase:	Night
Frequency:	All science frames
Purpose:	The strongest term in the optical-distortion model is the cubic
	radial term, but this and all distortions will be slightly colour (i.e.
	filter) dependent and must be determined on sky. The expected

VISTA		Document:	VIS-SPE-IOA-20000-0002

DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	35 of 72

Procedure	power of the distortion means that no practically useful jitter is possible without non-linear resampling. The radial scale distortion also has an impact on photometric measurements, inducing an error up to 3.5% in the corners of the field, compared to the centre, if uncorrected. It is thus crucial to determine it accurately. Astrometric stars in the science fields are used to map the

6.2.2 Final WCS Fit

Responsible: DFS calibration pipeline

Phase: Night

Frequency: All imaging frames on sky

Purpose: The camera software writes an initial WCS based on the given position of the guide star into the FITS headers of each data frame. The accuracy will be better than 2", dependent on the guide star accuracy, and the determined geometry of the camera. This provides a close starting point for orientation of the data frames and location of astrometric stars for a full WCS solution that will provide refined scientific quality astrometry. After instrumental-signature removal astrometric stars are centroided in the data frames to typically 0.1 pixels accuracy. An astrometric solution is carried out using reference catalogues based on the International Coordinate Reference Frame (ICRF) [e.g. 2MASS catalogue]. Accuracy is dependent on the reference catalogue accuracy, but the final uncertainty estimate comes from the RMS of the fit and the known systematics of the reference catalogue.

7 Quality Control

7.1 Further Quality Control Data Derived from Science Frames

7.1.1 Object Extraction

Responsible: Phase:	Science Operations
	Nearly all the time
1 2	Object extraction is vital for various steps in the pipeline,
1	including astrometric and photometric calibration, where the position and/or photometric measures of real objects are required. It is also needed in order to assess the quality of the data in terms of the observing conditions and the depth of exposure.
Procedure:	J C J
	algorithm. Classify objects as stellar, non-stellar and noise using the classification scheme. Use the stellar objects to work out the
	average properties of the images on the frame.
Raw Outputs:	FITS Files
Template:	-
OT queue:	Science
Pipeline Recipe:	vircam_jitter_microstep_process
Pipeline Output:	Mean sky background (QC)
	Mean sky noise (QC)
	Number of noise objects (QC)
	Mean seeing (QC)
_ ·	Mean stellar ellipticity (QC)
Duration:	Variable
Prerequisites:	
See Also:	

7.2 On line quality control (QC-0)

QC-0 is generic for all VLT-compliant instruments and is provided by the Data-Flow Operations group. All image-mode data produced by the instrument is fed into the pipeline to produce QC-1 parameters.

SYSTEM	Plan	Page:	38 of 72

7.3 Quality Control Parameters

Quality-control parameters are generated during pipeline processing. These may be used at a later time for trend analysis.

Parameter	Description
QC.APERTURE CORR 2	the aperture flux correction for stellar images due to
arcsec [mag] diam aperture	flux falling outside the aperture. Determined using a
flux correction.	curve-of-growth of a series of fixed-size apertures.
	Alternative simple measure of image profile
	properties, particularly the presence of extended PSF
	wings, as such monitors optical properties of system;
	also required for limiting magnitude computations.
QC.BAD_PIXEL_STAT	determined from the statistics of the pixel distribution
fraction of bad	from the ratio of two flatfield sequences of
pixels/detector [scalar].	significantly different average count levels. The
	fraction of bad pixels per detector (either hot or cold)
	should not change
QC.CROSS_TALK average	determined from presence of +ve or -ve ghost images
values for cross-talk	on other channels/detectors using exposures in bright
component matrix [scalar].	star fields. Potentially a fully populated 256x256
	matrix but likely to be sparsely populated with a small
	number of non-zero values of band-diagonal form.
	This QC summary parameter is the average value of
	the modulus of the off-diagonal terms. Values for the
	cross-talk matrix should be very stable with time,
	hardware modifications notwithstanding.
QC.DARKCURRENT	measured using the median of the pixel values, can
average dark current on	later be compared similar darks for trends
frame [adu/sec].	
QC.DARKDIFF_MED	Measure the median of the difference of a new mean
Median new-library dark	dark frame and a library reset frame.
frame [adu].	ware and the DMC of the difference of a new more dark
QC.DARKDIFF_RMS	measure the RMS of the difference of a new mean dark
[adu] RMS new-library dark frame	frame and a library dark frame.
QC.DARKMED median	median counts in dark frames.
dark counts	incular counts in dark frames.
QC.DARKRMS RMS noise	RMS is defined here as the Gaussian equivalent MAD
of combined dark frame	ie. 1.48*median-of-absolute-deviation from median
[adu].	The RMS can later be compared with library values for
	darks of the same integration and exposure times.
QC.ELLIPTICITY mean	the detected image intensity-weighted second moments
stellar ellipticity [scalar].	will be used to compute the average ellipticity of

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	39 of 72

	suitable signal:to:noise stellar images. Shot-noise causes even perfectly circular stellar images to have non-zero ellipticity but more significant values are
	indicative of one of: optical, tracking and autoguiding, or detector hardware problems.
QC.FLATRATIO_MED Median new/library flat frame [scalar].	Measure the median of the ratio of a new mean flat frame and a library flat frame.
QC.FLATRATIO_RMS RMS new/library flat frame [scalar].	Measure the RMS of the ratio of a new mean flat frame and a library flat frame.
QC.FLATRMS RMS flatfield pixel sens per detector [fraction].	RMS is defined here as the Gaussian equivalent MAD ie. 1.48*median-of-absolute-deviation from unity after normalising by median level ie. measuring the RMS sensitivity variation. The RMS can later be compared with library values for troubleshooting problems. significantly with time.
QC.FRINGE_RATIO [scalar] Ratio of sky noise before/after fringe fit	A robust estimate of the background noise is done before the first fringe fitting pass. Once the last fringe fit is done a final background noise estimate is done. This parameter is the ratio of the value before fringe fitting to the final value after defringing.
QC.GAIN gain [e/ADU].	determined from pairs of darks and flatfields of the same exposure/integration time and illumination by comparing the measured noise properties with the expected photon noise contribution. The gain of each detector should remain stable so long as the electronics/micro-code have not been modified.
QC.GAIN_CORRECTION detector median flatfield/global median [scalar].	the ratio of median counts in a mean flat exposure for a given detector relative to the ensemble defines the internal gain correction for the detector These internal relative detector gain corrections should be stable with time.
QC.ILLUMCOR_RMS	The RMS of the illumination correction over all the frame.
QC.IMAGE_SIZE mean stellar image FWHM [arcsec].	measured from the average FHWM of stellar-classified images of suitable signal:to:noise. The seeing will obviously vary over the night with time, wavelength (filter) and as airmass^0.6. This variation should be predictable given local site seeing measures. A comparison with the expected value can be used as an indication of poor guiding, poor focus or instrument malfunction.
QC.LIMITING_MAG limiting mag ie. depth of exposure [mag].	estimate of 5-sigma limiting mag for stellar-like objects for each science observation, derived from QCs ZPT_2MASS, SKY_NOISE, APERTURE_CORR. Can later be compared with a target value to see if

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	40 of 72

	main survey requirements (ie. usually depth) are met.
QC.LINEARITY	derived from measured non-linearity curves for each
percentage average non-	detector interpolated to 10k counts (ADUs) level.
linearity [percentage].	Although all infrared systems are non-linear to some
	degree, the shape and scale of the linearity curve for
	each detector should remain constant. A single
	measure at 20k counts can be used to monitor this
	although the full linearity curves will need to be
	examined quarterly [TBC] to look for more subtle
	changes.
QC.LINFITQUAL RMS	Derived by applying the linearity coefficients to the
fractional error in linearity	image data that were used to measure them. This is the
fit	RMS of the residuals of the linearised data normalised
	by the expected linear value
QC.MAGNZPT Number of	The number of stars on this image used to calculate the
stars in zero point cale.	photometric zeropoint.
QC.MAGZERR	A measure of the RMS photometric zero point error
Photometric zero point error	using an aperture of 1* the core radius.
[mag].	
QC.MAGZPT Photometric	A measure of the photometric zero point using an
zero point [mag].	aperture of 1* the core radius.
QC.MEAN_SKY mean sky	computed using a clipped median for each detector
level [ADU].	Sky levels (perhaps not at Ks) should vary smoothly
	over the night. Strange changes in values may indicate
	a hardware fault.
QC.NOISE_OBJ number of	measured using an object cataloguer combined with a
classified noise objects per	morphological classifier. The number of objects classified as noise from frame-to-frame should be
frame [number].	
	reasonably constant; excessive numbers indicate a problem.
QC.PARTICLE RATE	average no. of pixels rejected during combination of
cosmic ray/spurion rate	dark frames, used to give an estimate of the rate of
[count/s/detector].	cosmic ray hits for each detector. This can later be
	compared with previous estimates and monitored.
QC.PERSIST_DECAY	the decay rate of the persistence of bright images on
mean exponential time	subsequent exposures will be modelled using an
decay constant [s].	exponential decay function with time constant tau.
, . r_j.	Requires an exposure on a bright star field followed a
	series of darks.
QC.PERSIST_ZERO	determined from the persistence decay behaviour from
fractional persistence at T0	exponential model fitting. Requires an exposure on a
(extrapolated).	bright star field followed a series of darks (as above)
QC.READNOISE readnoise	measured from the noise properties of the difference in
[electron].	two consecutive dark frames, using a MAD estimator
	as above for robustness against spurions. The noise
	properties of each detector should remain stable so
	long as the electronics/micro-code have not been

	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	41 of 72

	modified.
QC.RESETDIFF_MED Median new-library reset	Measure the median of the difference of a new mean reset frame and a library reset frame.
frame [adu]. QC.RESETDIFF_RMS [adu] RMS new-library reset frame	measure the RMS of the difference of a new mean reset frame and a library reset frame.
QC.RESETMED median reset level	median reset level
QC.RESETRMS RMS noise in combined reset frame.	variation is defined here as the Gaussian equivalent MAD ie. 1.48*median-of-absolute-deviation from unity after normalising by median level ie. measuring the RMS reset level variation. The RMS can later be compared with library values for troubleshooting problems.
QC.SATURATION saturation level of bright stars [ADU].	determined from maximum peak flux of detected stars from exposures in a standard bright star field. The saturation level*gain is a check on the full-well characteristics of each detector.
QC.SKY_NOISE RMS sky noise [ADU].	computed using a MAD estimator with respect to median sky after removing large scale gradients. The sky noise should be a combination of readout-noise, photon-noise and detector quirks. Monitoring the ratio of expected noise to measured provides a system diagnostic at the detector level.
QC.WCS_DCRVAL1 actual WCS zero point X - raw header value [deg].	measure of difference between dead-reckoning pointing and true position of the detector on sky. Derived from current polynomial distortion model and 6-constant detector model offset.
QC.WCS_DCRVAL2 actual WCS zero point Y - raw header value [deg].	measure of difference between dead-reckoning pointing and true position of the detector on sky. Derived from current polynomial distortion model and 6-constant detector model offset.
QC.WCS_DTHETA actual WCS rotation PA - raw PA header value [deg].	measure of difference between dead-reckoning PA and true position angle of the detector. Derived from current polynomial distortion model and 6-constant detector model effective rotation term.
QC.WCS_RMS robust RMS of WCS solution for each detector [arcsec].	robust average of residuals from WCS solution for each detector. Measure of integrity of WCS solution.
QC.WCS_SCALE measured WCS plate scale per detector [deg/pixel].	measure of the average on-sky pixel scale of detector after correcting using current polynomial distortion model
QC.WCS_SHEAR power of cross-terms in WCS solution [deg].	measure of WCS shear after normalising by plate scale and rotation, expressed as an equivalent distortion angle. Gives a simple measure of distortion problems in WCS solution.

QC.ZPT_2MASS 1st-pass	the magnitude of a star that gives 1 detected ADU/s (or
photometric zeropoint	e-/s) for each detector, derived using 2MASS
[mag].	comparison stars for every science observation. This is
	a first pass zero-point to monitor gross changes in
	throughput. Extinction will vary over a night, but
	detector to detector variations are an indication of a
	fault.
QC.ZPT_STDS photometric	the magnitude of a star that gives 1 detected ADU/s (or
zeropoint [mag].	e-/s) for each detector, derived from observations of
	VISTA standard star fields. Combined with the trend
	in long-term system zero-point properties, the
	ensemble "average" zero-point directly monitors
	extinction variations (faults/mods in the system
	notwithstanding) The photometric zeropoints will
	undoutbedly vary (slowly) over time as a result of the
	cleaning of optical surfaces etc.

8 Templates

The hierarchy of the templates defined for VIRCAM are shown in Figure 8-1 below. There are a series of templates for each of the operating modes described in section 3. Note: the template definitions are refined from those presented in early drafts of this document to reflect enhancements in the final design of the camera observation software [RD6].

- Acquisition templates *(shown in blue italic)*, which define the operating mode and telescope target parameters. Each Observation Block begins with an acquisition template defining the primary target to which that Observation Block refers. Acquisition templates do not generate exposures.
- Calibration templates (shown in red), which obtain exposures necessary for calibrating observations in a particular instrument mode. A calibration template can result in one or more exposures being made.
- Observation templates (shown in black), which obtain the exposures necessary to make science observations. An observation template can result in one or more exposures being made.

Table 8-1 Relationship between Data Types, Observation Templates and Pipeline Recipes

8.1 Imaging Calibration Templates

8.1.1 Reset

Name:	Reset
Identifier:	VIRCAM_img_cal_reset.tsf
Description:	Make a number of reset frames (reset-read only) with cold
	blank (a single reset/read sequence). Used with HOWFS and
	IMAGING mode.
Parameters:	number of reset frames
Raw Frames:	FITS
Pipeline recipes:	vircam_reset_combine

8.1.2 Dark

Name:	Dark
Identifier:	VIRCAM_img_cal_dark.tsf
Description:	Make a number of dark exposures (reset-read-read) with cold
	blank
Parameters:	integration time, number of integrations, number of frames
Raw Frames:	FITS
Pipeline recipes:	vircam_dark_combine

8.1.3 Dark Current

Name:	Dark Current
Identifier:	VIRCAM img cal darkcurrent.tsf
Description:	Make a series of dark exposures at a variety of different exposure times
Parameters:	List of integration times, and corresponding numbers of integrations for determination of detector dark current.
Raw Frames:	Sequence of FITS files
Pipeline recipes:	vircam_dark_combine

8.1.4 Acquire Dome Screen

Name:	Dome Screen
Identifier:	VIRCAM_img_acq_domescreen.tsf
Description:	Set instrument into IMAGING mode and select science filter.
	Move telescope to point at illuminated screen and switch on
	lamps.
Parameters:	Filter, illumination combination
Raw Frames:	None
Pipeline recipes:	None

8.1.5 Dome Flat

Name:	Dome Flat
Identifier:	VIRCAM_img_cal_domeflat.tsf

VISTA	Calibration	Document:	VIS-SPE-IOA-20000-0002
		Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	48 of 72
Description:	suitable for of flat-field lan complete.	calibrating IMA	(or sequence of exposures) GING mode observations. The ched off when exposure is
Parameters:	Filter, list of integration times and corresponding numbers of integrations, switch calibration source off flag, lamp setting.		
Raw Frames:	FITS files		
Pipeline recipes:	vircam_dome_flat_combine		

8.1.6 Detector Linearity

Name:	Linearity
Identifier:	VIRCAM_img_cal_linearity.tsf
Description:	Make series of dome flat exposures and corresponding darks
	at a list of exposure times.
Parameters:	Filter, List of integration times and corresponding numbers of
	integrations
Raw Frames:	FITS files
Pipeline recipes:	vircam_linearity_analyse

8.1.7 Noise and Gain

Name:	Noisegain
Identifier:	VIRCAM_img_cal_noisegain.tsf
Description:	Make two dark exposures followed by the same number of dome screen flat-field exposures with matched integration times and number of integrations.
Parameters:	filter, optional: detector controller mode, list of integration times and corresponding number of integrations, lamp level, optional "switch off calibration source when finished".
Raw Frames: Pipeline recipes:	FITS Files vircam_detector_noise

8.1.8 Acquire Twilight Field

Name:	Twilight
Identifier:	VIRCAM_img_acq_twilight.tsf
Description:	Select a dusk or dawn twilight field (Figure 2-1). Track (no autoguiding).
Parameters:	filter, acceptable Azimuth, Altitude range for search, moon avoidance distance, optional: Azimuth, Altitude, rotator position angle.
Raw Frames:	None
Pipeline recipes:	None

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	49 of 72

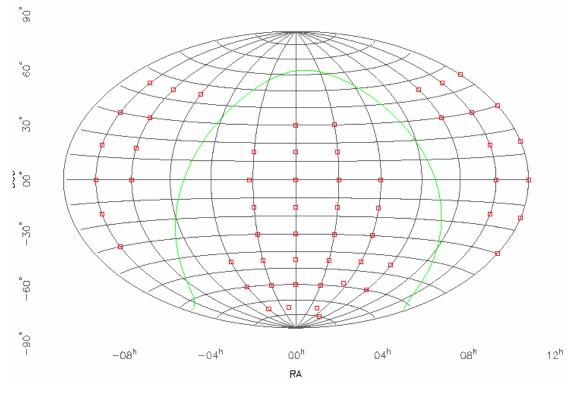

Figure 8-2 Pre-selected twilight fields

8.1.9 Twilight Flat

Name: Identifier: Description:	Twilight Flat VIRCAM_img_cal_twiflat.tsf Take a series of exposures sufficient to make a twilight sky flat-field, automatically determining exposure values. Move telescope in small offsets between integrations to reject bright
Parameters:	stars. List of integration times and corresponding numbers of integrations, or illumination level, depending on level of automation. Includes procedure to wait until sky brightness is appropriate, or abort if the time is too late (dusk and dawn).
Raw Frames: Pipeline recipes:	FITS files vircam_twilight_combine

8.1.10	Persistence
Name:	Persistence
Identifier:	VIRCAM_img_cal_persistence.tsf
Description:	Take one exposure with a selected science filter, followed by
	a series of dark exposures. All exposures have the same
	integration time and number of integrations. The field should
	contain a nearly-saturated star.
Parameters:	science filter, number of dark exposures, number of

	exposures, integration time, number of integrations.
Raw Frames:	FITS files
Pipeline recipes:	vircam_persistence_analyse

8.1.11 Astrometric Calibration

No specific astrometric calibration templates are required as all science frames will be calibrated according to the procedure described in 6.2.2.

8.1.12 Photometric Calibration Standard Fields

Name:	Calibrate
Identifier:	VIRCAM_img_cal_std.tsf
Description:	This template is identical to VIRCAM_img_obs_paw.tsf (see
	8.3.2 for full operational description) except for the insertion of
	FITS information indicating a photometric standard field
	(STANDARD = T). It is only necessary to observe a pawprint for
	calibration, a full tile is unnecessary.
Parameters:	Number of filter positions F, and (if F>1) filter IDs;
	Number of jitter positions J, Number of microstep positions M
	nested at each jitter position;
	(if $J > 1$) jitter pattern ID, jitter scale factor, and (if $M=1$) at each
	jitter position integration time, number of integrations;
	(if M>1) microstep pattern ID, microstep scale factor, and at each
	microstep position the integration time, number of integrations.
Raw Frames:	As many FITS files as there are exposures
Pipeline recipes:	vircam_standard_process

8.1.13 Quick look

Name:	quick look
Identifier:	VIRCAM_img_obs_exp.tsf
Description:	Make a series of exposures at the same target position with a
	single filter, with no jittering or microstepping.
Parameters:	science filter, number of exposures, integration time, number of integrations.
Raw Frames:	FITS files
Pipeline recipes:	None.

8.1.14 Cross-talk

Name:	Cross-talk
Identifier:	VIRCAM_img_cal_crosstalk.tsf
Description:	Make a series of exposures, with each exposure offset from
	the previous one by a sequence of meso-steps designed to
	place a bright star on each of the 16 readout channels on each
	detector.
Parameters:	science filter, optional list of meso-step offsets, optional

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	51 of 72

Raw Frames: Pipeline recipes:	detector mode, number of exposures, integration time, number of integrations. FITS files vircam_crosstalk_analyse
8.1.15 Illumir	nation
Name:	Illumination
Identifier:	VIRCAM_img_cal_illumination.tsf
Description:	make a series of exposures, with each exposure offset from the previous one by a sequence of meso-steps designed to place a bright star at a regular grid of offset positions across each detector.
Parameters:	List of science filters, list of mesostep offsets, list of [guide star plus two aO stars] for each mesostep in the sequence, optional detector mode, number of exposures, integration time, number of integrations.
Raw Frames:	FITS files
Pipeline recipes:	vircam_mesosteop_analyse

8.2 HOWFS mode calibration

HOWFS processing is carried out on the Instrument Workstation, and data is not passed on to the pipeline.

8.2.1 HOWFS Acquire Dome Screen

Name:	HOWFS Acquire Dome Screen
Identifier:	VIRCAM_howfs_acq_domescreen.tsf
Description:	Set camera into HOWFS mode and select HOWFS
	intermediate filter. Move telescope to dome illuminated screen, set tracking off and set illumination level.
Parameters:	Filter, screen illumination lamp combination.
Raw Frames:	None
IWS Procedures:	No
Pipeline recipes:	None

8.2.2 HOWFS Reset

Name:	HOWFS Reset
Identifier:	VIRCAM_howfs_cal_reset.tsf
Description:	Make a series of reset exposures suitable for calibrating
	HOWFS observations.
Parameters:	Filter (Dark), number of frames.
Raw Frames:	FITS
IWS Procedures:	Yes
Pipeline recipes:	None

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	52 of 72

8.2.3 HOWFS Dark

Name:	HOWFS Dark		
Identifier:	VIRCAM howfs cal dark.tsf		
Description:	Make several dark exposures suitable for calibrating HOWFS observations.		
Parameters:	Filter, integration time, number of integrations.		
Raw Frames:	FITS		
IWS Procedures:	Yes		
Pipeline recipes:	None		

8.2.4 HOWFS Dome Flat

Name:	HOWFS Dome Flat
Identifier:	VIRCAM_howfs_cal_domeflat.tsf
Description:	Make a flat-field exposure (or exposures) suitable for
	calibrating HOWFS observations.
Parameters:	Filter & illumination combination, integration time, number
	of integrations, focal plane X, Y, and detector window size.
Raw Frames:	FITS
IWS Procedures:	Yes
Pipeline recipes:	None

8.3 Imaging Mode Science Templates

The nesting of the observing loops is described in the same way as in the URD [AD2] using a shorthand based on the order of nesting of the loops for the 6 components, (F for filter, T for tile, P for pawprint, J for jitter, M for microstep, E for exposure), with the order of the letters indicating increasing nesting of the loop as one reads to the right.

8.3.1 Acquire

Name: Identifier: Description:	Acquire VIRCAM_img_acq.tsf Acquire single target. Check/Set camera to IMAGING mode, check/set camera position angle, check/select first science filter, all in parallel with a preset of telescope to new target, optionally (and usually) guide, optionally (and usually) activate LOWFS. The flat-field lamp is checked and automatically switched off when the telescope presets to a new celestial target.
	i.e. nest Preset to defined position Check/Set IMAGING mode in parallel Check/Set camera PA in parallel [default +X axis to +RA] Check/Set first filter in parallel If guiding required

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	53 of 72

	Acquire guide star LOWFS on two stars in parallel
Parameters:	Target coordinates,
	focal plane position to be at target position [e.g. centre of camera (default), or specified offset from centre of camera, or centre of a specified detector],
	camera position angle (E of N on sky, defaults to give +X to
	+RA),
	first filter,
	autoguiding required flag, if set (default) coordinates for 1 guide star from the SDT,
	LOWFS required flag, if set (default) 1 pair LOWFS stars found
	by the SDT.
Raw Frames:	None
Pipeline recipes:	None

8.3.2 Observe Paw

Name: Identifier: Description:	Observe VIRCAM_img_obs_paw.tsf This template makes one "pawprint" observation using a selection of filter changes, jittering and microstep movements. It is assumed the telescope has already been positioned at the target using the acquisition template. The detector controller is configured with the required readout and exposure times and the following sequence executed:
Parameters:	FJME step through science filters in outer loop. At each science filter execute a jitter pattern (if specified), and within each jitter pattern execute a microstep pattern (if specified) List of science filters
	Number of jitter positions, [optional: jitter pattern ID, jitter scale factor] Number of microstep patterns, [optional: microstep pattern ID, microstep scale factor] Number of exposures Integration time Number of integrations
Raw Frames: Pipeline recipes: Note:	[optional: New camera-position angle] As many FITS files as there are exposures vircam_jitter_microstep_process The pipeline handles microstepped and jittered exposures differently. To just perform exposures at a fixed position set J=1 and M=1 To just perform a jitter pattern with no microsteps set M=1 To just perform a microstep pattern with no jitters set J=1

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	54 of 72

8.3.3 Observe Tile

8.3.3 Observe Name: Identifier: Description:	Tile Observe Tile VIRCAM_img_obs_tile.tsf This template makes sufficient observations to generate a contiguous "tile", using a selection of pawprints, filter changes, jittering and microstep movements. It is assumed the telescope has already been pointed to the null target with the acquisition template. The detector controller is configured with the required readout and exposure time parameters and one of the following sequences executed: FPJME – Construct the tile from a series of pawprints, repeating each pawprint with a different science filter. Within each pawprint execute a jitter pattern (if specified), and within each
	jitter pattern execute a microstep pattern (if specified). PFJME – Construct the tile from a series of pawprints. Within each pawprint execute a jitter pattern, except, this time repeat each jitter with a different science filter before moving on to the next. Within each jitter, execute a microstep pattern (if specified). FJPME – Construct the tile from a pawprint and jitter pattern such that one jitter observation is made from each pawprint in turn. Within each jitter pattern there can be a microstep pattern. The whole sequence may be repeated with different science filters.
	Each time a new pawprint is selected, the TCS is provided with a new guide star and a new pair of LOWFS stars, taken from the list provided by the template.
	i.e. nest FPJME For each Filter For each pawprint position (1 to P) Check/offset telescope (steps 5-10') Acquire new guide and LOWFS stars For each jitter position (1 to J) Check/Move telescope (steps <30", same guide star) For each microstep (1 to M) Check/Move telescope (steps <3", same guide star) For each exposure (1 to E) Make exposure Next exposure Next microstep Next jitter Next pawprint Next Filter
Parameters:	Nesting pattern (FPJME, PFJME or FJPME as above) List of science filters Tile pattern ID, tile scale factor

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	55 of 72

	List of [guide star plus two HOWFS stars] for each pawprint in the tile pattern Number of jitter positions, [optional: jitter pattern ID, jitter scale
	factor],
	Number of microstep positions, [optional: microstep pattern ID,
	microstep scale factor]
	Number of exposures
	Integration time
	Number of integrations
Raw Frames:	As many FITS files as there are exposures
Pipeline Recipes:	vircam_jitter_microstep_process
Note	The pipeline handles microstepped and jittered exposures in a different way.

8.3.4 Observe Offsets

Name: Identifier:	Observe Offsets VIRCAM img obs offsets.tsf
Description:	Similar to Observe Tile except the offsets are not limited to a set
	of pre-defined offset patterns. The purpose is to allow the versatility of more general sets of offsets, rather than those offset pattern that have been predefined for produce a simple tile.
Parameters:	List of science filters
	Tile pattern ID
	Tile scale factor
	List of [guide star plus two LOWFS stars] for each offset
	List of RA, Dec offsets
	Number of exposures
	Integration time
	Number of integrations
	[optional: list of position-angle offsets]
Raw Frames:	(Number of pawprint locations × number of exposure in each pawprint) FITS files
Pipeline recipes:	vircam jitter microstep process
Note	Pipeline produces pawprints, these are not merged.

8.3.5 Observing a set of Tiles

Three templates (FTPJME, TFPJME and TPFJME) that observe more than one tile were outlined in the URD [AD2]. The template design has now been considerably streamlined such that the required behaviour can be realised with the observe-tile template, or with multiple templates within an OB.

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	56 of 72

8.4 HOWFS mode data

HOWFS processing is carried out on the Instrument Workstation, and data is not passed on to the pipeline.

8.4.1 HOWFS Acquire

Name:	HOWFS Acquire
Identifier:	VIRCAM_howfs_acq.tsf
Description:	Acquire a HOWFS (High-Order Wave Front Sensor) source.
	Set instrument into HOWFS mode which selects HOWFS
	intermediate filter. If guiding and LOWFS are required, set
	guide star and two LOWFS coordinate sets.
Parameters:	HOWFS filter
	Target coordinates and camera position angle
	[optionally: guide star, two LOWFS stars]
	focal plane X,Y
Raw frames:	None
IWS Procedures:	None
Pipeline recipes:	None

8.4.2 HOWFS Wave front

Name: Identifier:	HOWFS wave front VIRCAM howfs obs wfront.tsf
Description:	Make a HOWFS wave front measurement for measuring the current residual from the active optics lookup table. This will
	typically be done only \sim twice per night, once at the start of the night, and once around midnight if necessary.
Parameters:	HOWFS filter
	focal plane X,Y and detector window size
	integration time
	number of integrations
	[optional: max iterations, number of coefficients, name of
	file]
Raw Frames:	FITS
IWS Procedures:	Trigger HOWFS analysis system, forward coefficient residuals to TCS
Pipeline recipes:	None

8.4.3 HOWFS Expose

Name:	HOWFS Expose
Identifier:	VIRCAM_howfs_obs_exp.tsf

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	57 of 72
Description:	Make a HOWFS wave front measurement suitable for populating the active optics lookup tables in the TCS. This will be done only very occasionally [~quarterly] in engineering time and does not form part of the routine operations.		
Parameters:	HOWFS filter focal plane X,Y and detector window size integration time number of integrations [optional: max iterations, number of coefficients, name of file]		
Raw Frames:	FITS		
IWS Procedures:	Trigger HOWFS analysis system, produce look up table.		
Pipeline recipes:	None		

8.5 Instrument Health Templates

Instrument health monitoring templates are defined in [RD5] and are run on a regular basis. For example the instrument filter wheel is tested regularly for position repeatability, and this may determine how often to repeat a flat-field calibration with a particular science filter. The templates in [RD5] are not repeated here, since these monitoring outputs are not processed by the VISTA pipeline and hence are not described in this Calibration Plan.

VISTA		Document:	VIS-SPE-IOA-20000-0002

9 Technical Programs

9.1 TP-VIS1: Establishment of Secondary Standard Fields

This section outlines the procedures required to establish a network of secondary standard fields early in the operation of VIRCAM.

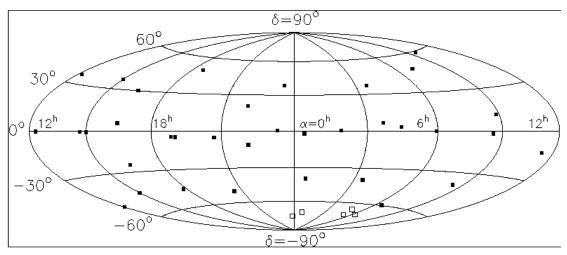

Figure 9-1 Distribution of the 2MASS touchstone fields on the sky

Name: Program Identifier: Purpose:	Secondary Standard Fields TP-VIS1-IMA-PHO-0001 Provide secondary standards for VISTA for routine calibrations (see Section 5)
Description:	A programme of observations around the primary standards is required to make direct measurements of all the secondary standards in the VIRCAM filter system. These observations will be repeated throughout the year to minimize the errors in the secondary star measurements, to identify variables, and to provide full coverage in Right Ascension. These fields are chosen to ensure photometric pedigree and are drawn from the list of 2MASS touchstone fields [RD9] and from published lists of photometric standards ([RD10], [RD11], [RD16]). Many of these fields are also WFCAM calibration fields. The secondary standard fields are tabulated in Appendix A.
Observing Conditions:	Photometric
Frequency:	Complete night at quarterly intervals over first 2 years of VIRCAM operations to ensure the photometric pedigree and accuracy of the standard fields
Special Conditions:	None
Analysis procedure:	A master catalogue of standard stars will be derived for each field with photometry in each of the VIRCAM filters.

VISTA		Document:	VIS-SPE-IOA-20000-0002
	Calibration	Date:	2006-09-28
DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	59 of 72

	Photometry will be measured using standard VFDS pipeline procedures [RD1].
Products:	Z, Y, J, H, K _S magnitudes of \sim 1500 secondary standards in
	each field
Accuracies:	The target is 0.005 magnitude rms for secondary standards
	in each waveband after two years of repeated observations.
Responsible Person:	JPE

DATA FLOW		Issue:	1.3
SYSTEM	Plan	Page:	60 of 72

10 Format of Data Frames

10.1 Principle

There is only one data format, used in both IMAGING and HOWFS modes. Data frames will be in ESO modified standard FITS format [RD12], the ESO modifications being limited to the *hierarchical header* proposal. The headers are compliant with the final World Coordinate System (WCS) specification [RD13]. Data from the full set of chips is stored in Multi Extension Format (MEF) as 32-bit signed integers [RD12], each extension corresponding to a particular detector. Offset 16-bit format is not used because data will be co-added in the data acquisition system before output. Though not a requirement, the integer format enables the use of highly efficient lossless compression.

10.2 Model FITS header

A model FITS header for raw data is presented in Table 10-1. In addition to the header shown in the model, standard pipelineprocessing keywords will be inserted into the data products.

```
SIMPLE =
                                                     T / Standard FITS format (NOST-100.0)
BITPIX =
                                                     8 / # of bits storing pix values
NAXIS
              _
                                                     0 / # of axes in frame
EXTEND =
                                                    T / Extension may be present
                                ,
                                                                        / European Southern Observatory
