Change Record

Issue	Date	Sections Affected	Reason/Initiation/Documents/Remarks	
1.0	2004-12-17	All	New Document	
1.1	2005-05-03	All	post-FDR revision	
1.2	2005-08-12	4	post DICB comments	
1.3	2005-12-25	All	Consistency with DRL v0.1, JRL, MJI, PSB updates	
1.4	2006-06-15	All	Many changes to all sections to help bring the document into line with DRL 0.3	
1.5	2006-09-28	0,5,6,7	Explanations of dummy products expanded. Expanded list of fatal and non-fatal errors for recipes. Many other smaller changes	
1.6	2006-12-20	2,6,8	Added vircam_destripe + description Added parameters to jitter_microstep_process. Many other smaller changes, including touch- ups to table 10-1 update QC & DRS dictionaries Update vircam_standard_process, modify vircam_jitter_microstep_process, and modify entries in table 10-1. Modified vircam_illum entry in chapter 6. Modified vircam_mesostep_analyse and vircam_defringe Spell check and added QC STRIPERMS

1 Introduction

This document forms part of the package of documents for the design of the Data Flow System for VISTA, the Visible and Infra-Red Survey Telescope for Astronomy.

1.1 Scope

This document describes the VISTA Infra-Red Camera Data Reduction Library Design for the output from the 16 Raytheon VIRGO IR detectors in the Infra Red-Camera for VISTA (VIRCAM). The baseline requirements for calibration are included in the VISTA Infra-Red Camera Data Flow System User Requirements [AD2], and the Calibration Plan is described in [AD3].

1.2 Applicable Documents

- [AD1] Data Flow for the VLT/VLTI Instruments Deliverables Specification, VLT-SPE-ESO-19000-1618, issue 2.0, 2004-05-22.
- [AD2] VISTA Infra Red Camera DFS Impact, VIS-SPE-IOA-20000-00001, issue 1.3, 2005-12-25.
- [AD3] VISTA Infra Red Camera DFS Calibration Plan, VIS-SPE-IOA-20000-00002, issue 1.3, 2005-12-25.
- [AD4] VISTA Infra Red Camera DFS Data Reduction Library Specification, VIS-SPE-IOA-20000-00003, issue 1.0, 2005-02-08.
- [AD5] Data Interface Control Document, GEN-SPE-ESO-19940-0794, issue 3, 2005-02-01.

1.4 Abbreviations and Acronyms

	•
2MASS	2 Micron All Sky Survey
ADU	Analogue to Digital Unit
CDS	Correlated Double Sampling
DFS	Data Flow System
DIT	Digital Integration
FITS	Flexible Image Transport System
FWHM	Full Width at Half Maximum
HOWFS	High-Order Wavefront Sensor
LUT	Look Up Table
MAD	Median Absolute Deviation from median
MEF	Multi-Extension FITS
NDR	Non-Destructive Read
RHS	Right Hand Side
RRR	Reset-Read-Read mode
VDFS	VISTA Data Flow System
VIRCAM	VISTA Infra Red Camera
VISTA	Visible and Infrared Survey Telescope for Astronomy
WCS	World Coordinate System
WFCAM	Wide Field Camera (on UKIRT)

1.5 Glossary

CDS

Correlated-Double Sampling; before the charge of each pixel is transferred to the output node of the detector, the output node is reset to a reference value. The pixel charge is then transferred to the output node. The final value of the charge assigned to this pixel is the difference between the reference value and the transferred charge.

Confidence Map An integer array, normalised to a median of 100%, which is associated with an image. Combined with an estimate of the

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	9 of 145

	sky background variance of the image, it assigns a relative
	weight to each pixel in the image and automatically factors in an exposure map. Bad pixels are assigned a value of 0. It
	is especially important in image filtering, mosaicing and
	stacking.
DAS	Data Acquisition System
DIT	Digital Integrations mean that separate readouts are summed digitally.
Exposure	The stored product of many individual integrations that
	have been co-added in the DAS. The sum of the integration
	times is the exposure time.
Integration	A simple snapshot, within the DAS , of a specified elapsed
T •44 (44)	time. This elapsed time is known as the integration time.
Jitter (pattern)	A pattern of exposures at positions each shifted by a small movement (< 20 arease) from the reference position. Unlike
	movement (<30 arcsec) from the reference position. Unlike a microstep the non-integral part of the shifts is any
	fractional number of pixels. Each position of a jitter pattern
	can contain a microstep pattern.
Mesostep	A sequence of exposures designed to completely sample
	across the face of the detectors in medium-sized steps, in
	order to monitor residual systematics in the photometry.
Microstep (pattern)	A pattern of exposures at positions each shifted by a very
	small movement (<3 arcsec) from the reference position. Unlike a jitter the non-integral part of the shifts are exact
	fractions of a pixel, which allows the pixels in the series to
	be interlaced in an effort to increase resolution. A microstep
	pattern can be contained within each position of a jitter
	pattern.
OB	Observation Block
Object	In the context of image analysis, an astronomical object.
Pawprint	16 non-contiguous images of the sky produced by
	VIRCAM with its 16 non-contiguous chips (see Fig 2-2 of [AD2]). The name is from the similarity to the prints made
	[AD3]). The name is from the similarity to the prints made by the padded paw of an animal (the terminology was more
	appropriate to 4-chip cameras).
Preset	A telescope slew to a new position requiring a
	reconfiguration of various telescope systems.
Robust Estimate	A statistical estimator that is resilient to small perturbations
	on the assumed shape of the underlying distribution.
Tile	A filled area of sky fully sampled (filling in the gaps in a
	pawprint) by combining multiple pawprints . Because of the detector spacing the minimum number of pointed
	the detector spacing the minimum number of pointed observations (with fixed offsets) required for reasonably
	uniform coverage is 6, which would expose each piece of
	sky, away from the edges of the tile, to at least 2 camera
	pixels. The pipeline does not combine pawprint s into tiles.

2 Mathematical Description

In this section we include a mathematic description of some of the methods we will use to calibrate and correct data from VIRCAM. The main technical challenges in processing VISTA data stem from the fact that: IR detectors are currently inherently more unstable than their optical counterparts; the sky emission, roughly 100 times brighter than most objects of interest, varies in a complex spatial and temporal manner; and the large data volume that arises from NIR mosaic cameras. To minimise the subsequent data volume several basic pre-processing steps will be carried out in the VISTA data-acquisition system, including reset-correction and co-addition of successive DITs from the same exposure.

The first stage of the VDFS pipeline will be to apply a linearity correction as outlined in section 2.2. Subsequent processing steps including: dark and reset-anomaly correction; flat-fielding and inter-channel gain correction; and sky artefact removal (e.g. fringe patterns), are designed to remove the instrumental and residual sky signatures from the images.

The algorithms used in the VIRCAM pipeline are the result of 25 years development in the analysis of digital images. An excellent and detailed review of the mathematical techniques involved in wide-field image analysis is given in [RD 9]. In particular, the robust estimator is detailed and an in-depth description of image detection and parameterization, as used in section 2.14, is given. Several of the effects included in this section may not even exist in VIRCAM data; it is prudent however to make arrangements for dealing with such issues if early experience with the data shows the effects to be present.

We outline in the following sections the salient points of the mathematical operations to be performed, for further detail see [AD2], [AD3] and [AD4].

2.1 Reset Correction

As with most electronic detectors infrared detectors are given a pedestal bias level by the driving electronics. As such the first step in any reduction of such data is to remove that bias. For VIRCAM this will be done in the DAS. This removes the need for explicit bias removal in the pipeline.

2.2 Non-Linearity

The Calibration Plan [AD3] lays out the necessity and the methodology for calibrating and correcting for the expected non-linearity in the response of the detector system to incident radiation.

2.2.1 Correcting for non-linearity

In default CDS reset-read-read (RRR) mode, downstream of the data acquisition system (DAS) the output that we see is

$$\Delta I' = I'_2 - I'_1 = f(I_2) - f(I_1)$$
(2-1)

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	11 of 145

where I'_1 and I'_2 denote the non-linear first (i.e. the reset-frame) and second readouts respectively and I_1 and I_2 the desired linear quantities. The non-linear function f(I)maps the distortion of the desired linear counts to the non-linear system I'. If we define the inverse transform g(I') that maps measured counts I' to linearized counts Ias the inverse operator $g() = f^{-1}()$ then

$$I = g(I')$$
 and $I_1 = g(I'_1) \ I_2 = g(I'_2)$ (2-2)

If I'_1 and I'_2 were directly available this is a one-to-one mapping and can be done efficiently and accurately using Look Up Tables (LUT). This is the conventional way of implementing the correction prior to other image manipulation operations. However, if I'_1 and I'_2 are not separately available and all we have to work from is the difference $\Delta I'$ then a simple LUT transformation is not possible.

For example, taking the simplest case where the illumination level across the detector has not changed during the course of the RRR and no on-board co-addition is happening then, in principle given only ΔI and knowledge of the timing of the RRR operations we can deduce I_1 and I_2 by using the effective integration time for each to estimate their scaling to the measured difference ΔI such that,

$$I_1 = k\Delta I \text{ and } I_2 = (1+k)\Delta I \tag{2-3}$$

Unfortunately, the ratio k will not be constant for the non-linear quantities I'_1 and I'_2 forcing us to adopt a scheme along the following lines.

Given $\Delta I'$ and defining the non-linear operator f() as a polynomial with coefficients a_m (typically up to quartic) we have

$$\Delta I' = \sum_{m} a_{m} (I_{2}^{m} - I_{1}^{m}) = \sum_{m} a_{m} [(1+k)^{m} \Delta I^{m} - k^{m} \Delta I^{m}]$$
(2-4)

The quantity we want ΔI is buried in the non-linearity of the RHS and we have to solve an equation like this for every pixel. This is possible, and relatively simple to program using something like a Gauss-Seidel iterative scheme, but is more inefficient than a direct mapping.

If we wanted to use a completely general LUT approach we would require a 2D LUT for all possible values of I_1 and I_2 i.e. $65k \times 65k$ in size, or 4.3×2 Gbytes. Most likely we would need a different correction for each "channel" making a total of 256×8.6 Gbytes = 2.2 Tbytes of LUT for the VIRCAM! Of course if the range of values of *k* is limited via exposure time quantisation this decreases the size of the total number

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	12 of 145

of LUTs required considerably for the constant illumination case, but would be an ugly and possibly impractical solution.

Practical considerations (e.g. data volume), suggest two alternative solutions for nonlinearity correction: either correct the individual frames directly in the DAS by measuring and downloading the appropriate LUTs, or polynomial coefficients, to the DAS; or use a non-linear inversion on the reset-corrected frames as outlined here. This methodology is not generally applicable, e.g. to multi-NDR/gradient fitting readouts, but is directly applicable to co-added (or co-averaged) frames of the same exposure times, assuming constant illumination over the series.

For reset-corrected data, the non-linear inversion is competitive with complex operations on LUTs and much simpler to implement. It also has the added advantage of removing all aspects of the non-linearity correction from the DAS. The main disadvantages are the method is restricted to CDS RRR mode, and if the illumination level is rapidly varying (e.g. twilight) the effective scale factors k_i may be hard to compute accurately - although for all realistic practical situations the knock-on effect is likely to be negligible.

2.2.2 Measuring non-linearity

If all that is available are reset-corrected data from say a time series of dome flats, it is still feasible to directly compute the non-linearity coefficients.

Given a series of measurements $\{i\}$ of $\Delta I'_i$ and using the previous notation and polynomial model

$$\Delta I'_{i} = \sum_{m} a_{m} (I_{2}^{m} - I_{1}^{m}) = \sum_{m} a_{m} \Delta I_{i}^{m} [(1 + k_{i})^{m} - k_{i}^{m}]$$
(2-5)

where k_i are the exposure ratios under the constant illumination. In general $\Delta I_i = st_i$ where t_i is the exposure time of the *i*th reset-corrected frame in the series and *s* is a fixed (for the series) unknown scale factor. The k_i are computable from a knowledge of the exposure times and the reset-read overhead, t_i and $\Delta I'_i$ are measured quantities leaving the polynomial coefficients a_m and the scaling *s* to be determined. Thus the model is defined by

$$\Delta I'_{i} = \sum_{m} a_{m} (I_{2}^{m} - I_{1}^{m}) - \sum_{m} a_{m} s^{m} t_{i}^{m} [(1 + k_{i})^{m} - k_{i}^{m}]$$
(2-6)

and can be readily solved by standard linear least-squares methods using the following sleight-of-hand. Since the scaling *s* and hence the polynomial solution a_m are coupled, by simply (and logically) requiring in the final solution $a_1 = 1$, computation of *s* can be completely avoided.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	13 of 145

Rewriting the previous equation in the following form makes this more apparent

$$\Delta I'_{i} = \sum_{m} (a_{m} s^{m}) t_{i}^{m} [(1+k_{i})^{m} - k_{i}^{m}] = \sum_{m} b_{m} t_{i}^{m} [(1+k_{i})^{m} - k_{i}^{m}]$$
(2-7)

where now b_m are the coefficients to be solved for. The final step is to note that

$$a_m = b_m / s^m = b_m / b_1^m$$
 (2-8)

since by definition $a_1 = 1$.

2.3 Gain Correction

In the case of a single detector camera the mean flat field image is normalised to a value of 1. This ensures that when the flat field correction is done the average counts in the output image is the same as in the input. For multi-detector instruments, we normalise the mean flat field image for each detector by:

$$V = \frac{\sum_{i=1}^{n} \langle I \rangle_{i}}{N}$$
(2-9)

where $\langle I \rangle_i$ is a robust estimate of the average flux in the combined flat field image for the *i*th detector. Normalising in this way ensures that when doing flat field correction we also include a factor that removes the differences in mean gain of each detector.

2.4 Measurement of Read Noise and Gain

The read noise and gain can be measured using two dome flat frames of similar illumination and two similarly observed (in terms of exposure and integration times) dark frames. Forming the difference of the two flat frames gives a variance for the difference frame σ_f^2 . Doing the same for the two dark frames yields σ_d^2 . If the background means of the flat and dark frames are: m_{f1} , m_{f2} and m_{d1} , m_{d2} the local gain in electrons per ADU is:

$$\varepsilon = ((m_{f1} + m_{f2}) - (m_{d1} + m_{d2})) / (\sigma_f^2 - \sigma_d^2)$$
(2-10)

and the readout noise in electrons is

$$\sigma_{ro} = \varepsilon \sigma_d / \sqrt{2}$$
 (2-11)

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 obigi	Date:	2006-12-12
System		Page:	14 of 145

2.5 Dark-correction, flat-fielding and sky-correction

If the fringe spatial pattern is stable and if flat fields can be generated without fringing present, it is possible to decouple sky correction and fringe correction and apply a defringing method similar to the one we have developed for optical imaging [RD 11]. This involves creating a series of master fringe frames which are scaled by a suitable factor for each object frame. The scale factors are adjusted to minimise the fringe pattern in the processed frame.

Standard NIR processing recipes often subtract sky first and then flat-field. We can see why this can be advantageous compared with dark-correcting, flat-fielding and sky-correcting by considering the following encapsulation of the problem

$$D(x, y) = ff(x, y)[S(x, y) + F(x, y) + O(x, y) + T(x, y)] + dc(x, y)$$
(2-12)

where D(x, y) is observed, ff(x, y) is the flat-field function, S(x, y) is the sky illumination, F(x, y) is the fringe contribution, O(x, y) is the object contribution, T(x, y) is the thermal contribution, dc(x, y) is the dark current, and without loss of generality we have excluded any explicit wavelength and time-dependence for clarity.

Stacking a series of dithered object frames with rejection produces an estimate of the terms

$$\hat{I}(x,y) = ff(x,y)[S(x,y) + F(x,y) + T(x,y)] + dc(x,y)$$
(2-13)

therefore,

$$D(x, y) - \hat{I}(x, y) = ff(x, y)O(x, y)$$
(2-14)

obviating the need for dark-correcting and fringe removal as both separate data gathering requirements and as separate data processing steps; and minimising the effect of systematic and random errors in the flat-field function by removing the largest potential error terms.

In the event that the dark correction stage fails to remove the reset anomaly completely, the residual background variation is analogous to the problem of dealing with short-term variations in sky structure and can be dealt with using the methodology above.

The caveats here of course are that this method may well remove parts of large extended objects, large area nebulosity, and large low surface brightness objects and so on, unless suitable offset skies are used in the sky frame construction. Unfortunately this then opens the door for spatial and temporal variability of the sky background, leaving residual patterns.

The optimal strategy to use depends on the stability of the flat-fields, and the time constants for sky fringe pattern variations, and will be dealt with by assessing these characteristics during commissioning and then invoking suitable processing recipes.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	15 of 145

The alternative is to treat the dark correction dc(x, y), flat field ff(x, y), and fringe pattern F(x, y), as accurately known master library frames, in which case data processing involves solving the following variant of the problem

$$D(x, y) = ff(x, y) [S(x, y) + k.F(x, y) + O(x, y) + T(x, y)] + dc(x, y)$$
(2-15)

where k is a scale factor to be determined by the fringe-removing algorithm. In this case applying the master frames leads to

$$D'(x, y) = S(x, y) + O(x, y) + T(x, y)$$
(2-16)

reducing the problem to one of detecting astronomical objects on an additive, slowly spatially varying, background. This could be the method of choice for analysing large scale astronomical surface brightness variations.

2.6 Stripe Removal

AIT data from the VIRCAM detectors has shown a low level medium frequency stripe pattern. The stripes are perpendicular to the readout direction and are the same for all channels in a detector. This means that they can be modelled out by calculating the median of each row (ignoring any bad or object pixels) to form a one dimensional stripe profile. The stripe profile is normalised to zero median. This ensures that once the stripes are subtracted the median background level with remain the same. Each point in the normalised stripe profile is used to correct the relevant row in the input data.

2.7 Fringe Removal

Atmospheric emission lines may cause interference fringes to be present in the sky background at the level of a few percent of sky. Since the fringes can have complex spatial structures on a range of physical scales on the detector, removing them successfully is a multi-stage process.

First we note that fringing is an additive effect, so if removed as part of a procedure that used night sky data as a flat field source, this would introduce a systematic error in the photometry. To perform sky fringe removal effectively requires the flat fielding to be decoupled from the defringing by, for example, using twilight sky exposures to construct the flat-field frames, where the contribution from sky emission lines is negligible.

Consequently, the first stage of the process is to flat-field the dark sky science data correctly and to use a sequence of offset sky exposures to construct a fringe frame. These input frames are combined after suitable scaling to match the background levels and sigma-clipping to remove astronomical objects.

The defringing process then requires solving for the fringe scale factor k in the following equation:

$$D(x, y) = S(x, y) + kF(x, y) + O(x, y) + T(x, y)$$
(2-17)

where S is the sky contribution, O is the astronomical object contribution and T is the contribution from the thermal background.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	16 of 145

Since the fringe pattern is characterised by more rapidly varying spatial structure than the sky and thermal contributions, the overall background variation on the target and fringe frame is temporarily removed by use of a robust low-pass filter such that:

$$D'(x, y) \approx kF(x, y) + O(x, y)$$
(2-18)

The objects are localised, therefore a simple robust background noise estimator based on the Median of the Absolute Deviation (MAD) from the median can be used iteratively to find the scale factor k that minimises the background noise in D'(x, y). Allowing the scale factor to vary ensures that the relative contribution of the sky emission lines, which may vary in strength, is correctly dealt with.

More complex options involving decomposing the seasonal fringe patterns into eigenfringe maps may be required at later stages in the processing but this is outside of the scope of the standard calibration pipeline.

The success, or otherwise, of fringe removal is monitored by the computed fringe map scale factor and also by a robust measure of the change (ratio) of the global background noise/variation after fringing. This is encoded in the FRINGE_RATIO QC1 parameter.

2.8 Image persistence

Astronomical images, and artefacts from preceding frames, can persist and be present on the current image. Strategies for dealing with this involve assessing the time decay characteristics and adjacency effects (i.e. image spreading) if present. In the case of no image adjacency effects, correcting for image persistence will either involve updating and maintaining a persistence mask (for combination with the confidence map), or accumulating with suitable temporal decay, a persistence map, running over a night if necessary, to subtract from the current image. For example, in the simplest case

$$I_{k}^{obs}(x, y, t) = I_{k}^{true} + f \times I_{k-1}^{obs}(x, y, t - \Delta t) \times e^{-\Delta t/\tau}$$
(2-19)

where k is the image sequence number, f is the fraction of the image persisting after frame reset(s), Δt is the time interval between frames, and τ is the persistence decay constant which may be different for each detector.

It is possible that image persistence may include some sort of adjacency effects. These will have to be characterised at commissioning.

2.9 Crosstalk

Images from one detector channel may produce secondary images (ghosts) on other channels either positive or negative in sign and may also even cross from one detector to another. In a stable environment, it is feasible to measure the contribution of crosstalk from one channel to another by using bright point-like sources, and thereby define a comprehensive crosstalk matrix $C_{j,k}$. Since this is environment specific, determining the final form of this matrix will be one of the commissioning tasks, although earlier laboratory-based measurements will be used to characterise its likely impact and to investigate ways of minimising the effect.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	17 of 145

Providing the cross-talk terms are small (i.e. <1%, the most likely scenario), then the following simple single-pass additive correction scheme will be used to correct for this problem,

$$I'_{j} = I_{j} - \sum_{k \neq j} I_{j} C_{j,k}$$
(2-20)

where I_j is the observed frame and I'_j the corrected version. The typical error in making a single pass correction is approximately $\langle C_{j,k} \rangle_{j \neq k}^2$, which governs the requirement on the magnitude of the cross-talk terms. Note also that the matrix *C* will in general not be symmetric.

2.10 Astrometric Calibration

From the optical design studies of VISTA we know that, to a good approximation, the astrometric distortion shows negligible variation with wavelength and is well described by a radially symmetric polynomial distortion model of the form

$$r_{true} = k_1 \times r + k_3 \times r^3 + k_5 \times r^5 + \dots$$
(2-21)

where r_{true} is an idealised angular distance from the optical axis, r is the measured distance, and k_1 is the scale at the centre of the field, usually quoted in arcsec/mm. VISTA will have a central field scale, i.e. k_1 value of roughly 17.09 arcsec/mm. The term due to k_5 is usually negligible and, until real sky data is available, is not worth pursuing, since other similarly sized distortions may be present. Dropping this term and rearranging the preceding equation to a more convenient form gives

$$r_{true} = r' \times (1 + \frac{k_3}{k_1^3} \times r'^2) = r' + k \times r'^3$$
(2-22)

where r' is the measured distance from the optical axis in arcsec using the k_1 scale. If we convert all units to radians the "r-cubed" coefficient is conveniently scaled (in units of radians/radian³) and has a theoretical value of around 42 for VISTA, but will have a slight wavelength dependence.

Although this type of distortion generally presents no problem for accurate calibration of individual pointings, it can lead to various complications when stacking data taken at various locations, e.g. dither sequences. This is caused by the differential non-linear distortions across individual detectors being comparable to, or larger than, the pixel size of the detector. In these cases stacking involves resampling and interpolation of some form. While these are inevitable in combining pointings to form contiguous tiled regions, they may be avoided at earlier stages, such as stacking individual detector dither sequences, by suitably limiting dither offsets and thereby both simplify and speed up the data processing.

The effective scale due to the radial distortion is given by

$$dr_{true} / dr' = 1 + 3k \times r'^2$$
(2-23)

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	18 of 145

which describes the local change in relative pixel scale as a function of radial distance. For example, for VISTA at 0.8 degree radius, the differential distortion term is about 2.5%. This means that a 10 arcsec shift in the centre corresponds to a 10.25 arcsec shift at the outer corners of the arrays. For the outer detectors a large fraction of this distortion occurs across individual detectors.

In anticipation of this problem, we will implement a range of interpolation schemes that offer a trade off between maintaining independent pixel noise and resolution degradation.

For further information see the report at

http://www.ast.cam.ac.uk/vdfs/docs/reports/astrom/.

2.11 World Coordinate System

We intend, at least initially, to characterise the WCS using the ZPN projection [RD 7] and [RD 8], i.e. ARC + polynomial distortion, using a 3^{rd} order parameterisation (equation 2.22). The coefficients for this are encoded in the FITS header using the keywords PV2_1 and PV2_3.

2.12 Effect of Scale Change on Photometry

In addition to astrometric effects the change in scale as a function of radius also has photometric implications. The aim of conventional flat fielding is to create a flat background by normalising out perceived variations from (assumed) uniformly illuminated frames. If the sky area per pixel changes then this is reflected in a systematic error in the derived photometry.

However, since it much simpler to deal with "flat" backgrounds, this problem is either usually ignored or corrected during later processing stages, together with other systematic photometry effects. The effect is simplest to envisage by considering what happens to the area of an annulus on sky when projected onto the detector focal plane. The sky annulus of $2\pi sds$ becomes $2\pi r'dr'$ on the detector, which using k to denote k_3/k_1 leads to a relative area of

$$(1 + k \times r'^2).(1 + 3k \times r'^2) \approx (1 + 4k \times r'^2)$$
 (2-24)

or in other words roughly $4 \times$ the linear scale distortion.

However, since other more unpredictable factors, such as scattered light, will also play a significant role, it is simpler procedurally to bundle all the effects together and correct all the photometric systematics in one operation. The VDFS calibration plan [AD3] describes a procedure for achieving this as an illumination correction.

2.13 Confidence Maps

We define a confidence map c_{ij} as a normalised¹ i.e. $\langle c_{i,j} \rangle_j = 1$ inverse variance weight map denoting the "confidence" associated with the flux value in each pixel *j* of

¹ In practice we use a 16-bit integer map such that the median level is 100%

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	19 of 145

frame *i*. This has the advantage that the map is always finite and can also be used to encode for hot, bad or dead pixels, by assigning zero confidence. Furthermore, after image stacking the confidence map also encodes the effective relative exposure time for each pixel, thereby preserving all the relevant intra-pixel information for further optimal weighting.

The initial confidence map for each frame is derived from regular analysis of the master calibration flat-field and dark frames and is unique for each filter/detector combination due to the normalisation. As such it also encodes individual pixel sensitivities and also allows, for example, vignetted regions to be correctly weighted when combining frames. To use the confidence maps for weighted co-addition of frames then simply requires an overall estimate of the average noise properties of the frame. This can readily be derived from the measured sky noise, in the Poisson noise-limited case, or from a combination of this and the known system characteristics (e.g. gain and readout noise).

All processed frames (stacked individual detectors, tiled mosaiced regions) have an associated derived confidence map which is propagated through the processing chain in the following manner.

Defining the signal s_i in frame *i* with respect to some reference signal level s_{ref} as $s_i = f_i s_{ref}$, where f_i denotes the relative throughput (which in photometric conditions would be ∞ exposure time), the optimum weight to use for combining the *j*th pixel of (suitably aligned) frames i in order to maximise the signal:to:noise of sky-limited objects is defined by

$$x'_{j} = \frac{\sum_{i} w_{ij} x_{ij}}{\sum_{i} w_{ij}} \qquad \qquad w_{ij} = c_{ij} f_{i} / \sigma_{i}^{2}$$
(2-25)

where σ_i^2 is the average noise variance in frame *i*, x_{ij} is the flux in pixel *j* on the *i*th frame and x'_j is the combined output flux. The effective exposure time is that of s_{ref} .

The output confidence map, which is $\propto output noise_j^{-2}$, is therefore given by

$$c'_{j} = \frac{\left(\sum_{i} c_{ij} f_{i} / \sigma_{i}^{2}\right)^{2}}{\sum_{i} c_{ij} f_{i}^{2} / \sigma_{i}^{2}}$$
(2-26)

Special cases of this occur when $f_i = 1$, e.g. equal length exposures in stable photometric conditions, or the more general Poisson noise limited case, when $f_i / \sigma_i^2 = 1$, and the special variant of this when $f_i = 1$. These cases are given below, prior to renormalisation.

$$c'_{j} = \sum_{i} c_{ij} / \sigma_{i}^{2} \qquad c'_{j} = \frac{\left(\sum_{i} c_{ij}\right)^{2}}{\sum_{i} c_{ij} f_{i}} \qquad c'_{j} = \sum_{i} c_{ij} \qquad (2-27)$$

2.14 Catalogue generation

In order to provide quality control, and astrometric and photometric calibration information, it is necessary to generate detected object (i.e. stars, galaxies) catalogues for each target frame.

The catalogue generation software (e.g. [RD 12], [RD 9]) will make direct use of the confidence maps for object detection and parameterisation, and will produce the requisite information via the use of standard object descriptors. For completeness we give here a brief description of how this will be accomplished by use of the following steps:

- estimate the local sky background over the field and track any variations at adequate resolution to eventually remove them;
- detect objects/blends of objects and keep a list of pixels belonging to each blend for further analysis;
- parameterise the detected objects, i.e. perform astrometry, photometry and some sort of shape analysis.

2.14.1 Background analysis and object detection

The possibly-varying sky background is estimated automatically, prior to object detection, using a combination of robust iteratively-clipped estimators.

Any variation in sky level over the frame will be dealt with by forming a coarsely sampled background map grid. Within each background grid pixel, typically equal to 64×64 image pixels, an iteratively k-sigma clipped median value of "sky" will be computed based on the histogram of flux values within the grid pixel zone. A robust estimate of sigma can be computed using the Median of the Absolute Deviation (MAD) from the median (e.g. [RD 13]). This will then be further processed to form the frame background map (e.g. [RD 9]).

After removing the, possibly, varying background component, a similar robust estimate of the average sky level and sky noise per pixel can be made. This forms part of the quality control measures and also helps to robustly determine the detection threshold for object analysis.

Individual objects will be detected using a standard matched filter approach (e.g. [RD 12]). Since the only images difficult to locate are those marginally above the sky noise, assuming constant noise is a good approximation (after factoring in the confidence map information) and the majority of these objects will have a shape dominated by the point spread function (PSF), which thereby defines the filter to use.

2.14.2 Image parameterisation

The following image parameters can be computed efficiently and are directly used as part of the image quality control and calibration analysis.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	21 of 145

Isophotal Intensity - the integrated flux within the boundary defined by the threshold level; i.e. the 0^{th} object moment

$$I_{iso} = \sum_{i} I(x_i, y_i)$$
(2-28)

For Gaussian images, this is related to the total intensity by the factor $(1 - I_t / I_p)^{-1}$, where I_p is the peak flux and I_t the threshold level (all relative to sky).

Position - computed as an intensity-weighted centre of gravity; i.e. 1st moment

$$x_{0} = \sum_{i} x_{i} I(x_{i}, y_{i}) / \sum_{i} I(x_{i}, y_{i})$$

$$y_{0} = \sum_{i} y_{i} I(x_{i}, y_{i}) / \sum_{i} I(x_{i}, y_{i})$$
(2-29)

Covariance Matrix - the triad of intensity-weighted 2nd moments is used to estimate the eccentricity/ellipticity, position angle and intensity-weighted size of an image

$$\sigma_{xx} = \sum_{i} (x_{i} - x_{0})^{2} . I(x_{i}, y_{i}) / \sum_{i} I(x_{i}, y_{i})$$

$$\sigma_{xy} = \sum_{i} (x_{i} - x_{0}) . (y_{i} - y_{0}) . I(x_{i}, y_{i}) / \sum_{i} I(x_{i}, y_{i})$$

$$\sigma_{yy} = \sum_{i} (y_{i} - y_{0})^{2} . I(x_{i}, y_{i}) / \sum_{i} I(x_{i}, y_{i})$$
(2-30)

The simplest way to derive the ellipse parameters from the 2nd moments is to equate them to an elliptical Gaussian function having the same 2nd moments. It is then straightforward to show (e.g. [RD 14]) that the scale size, $\sqrt{\sigma_{rr}}$, is given by $\sigma_{rr} = \sigma_{xx} + \sigma_{yy}$; the eccentricity, $ecc = \sqrt{(\sigma_{xx} - \sigma_{yy})^2 + 4.\sigma_{xy}^2} / \sigma_{rr}$; and the position angle, θ is defined by, $\tan(2\theta) = 2.\sigma_{xy} / (\sigma_{yy} - \sigma_{xx})$. The ellipticity, *e*, which is simpler to interpret for estimating potential image distortions (e.g. trailing), is related to the eccentricity by $e = 1 - \sqrt{(1 - ecc)/(1 + ecc)}$

Areal Profile - a variant on the radial profile, which measures the area of an image at various intensity levels. Unlike a radial profile, which needs a prior estimate of the image centre, the areal profile provides a single pass estimate of the profile

$$ArealProfile \rightarrow T + p_1, T + p_2, T + p_3, \dots, T + p_m$$
(2-31)

where p_j ; j = 1,...m are intensity levels relative to the threshold, *T*, usually spaced logarithmically to give even sampling.

The peak height, I_p , is a useful related addition to the areal profile information and is defined as

$$I_{p} = \max[I(x_{i}, y_{i})]_{i}$$
(2-32)

or alternatively measured by extrapolation from the areal profile if the image is saturated. The areal profile provides a direct method to estimate the seeing of objects

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	22 of 145

in an image by enabling the average area of stellar images (point sources) at half the peak height, $\langle A \rangle$, to be estimated. The seeing, or FWHM, is then given by *FWHM* = $2\sqrt{\langle A \rangle / \pi}$.

Finally a series of aperture fluxes are required for object morphological classification (see below).

Aperture flux is defined as the integrated flux within some radius r of the object centre

$$I_{ap}(r) = \sum_{i \in r}^{N} I_i - N \times sky$$
(2-33)

Where boundary pixels are weighted pro-rata (soft-edged aperture photometry). A series of these is used to define the curve-of-growth, $I_{ap}(r)$ -v- r, for each object.

2.14.3 Morphological Classification

The object detection software will produce a series of background-corrected flux measures for each object in a set of "soft-edged" apertures of radius r/2, $r/\sqrt{2}$, r, $\sqrt{2r}$, 2r 32r, where r is typically fixed as the median seeing for the site+telescope+camera. The average curve-of-growth for stellar images is used to define automatically an aperture correction for each aperture used and also forms the basis for object morphological classification (required for isolating stellar images for seeing and trailing quality control).

The curve-of-growth of the flux for each object is compared with that derived from the (self-defining) locus of stellar objects, and combined with information on the ellipticity of each object, to generate the classification statistic. This statistic is designed to preserve information on the "sharpness" of the object profile and is renormalised, as a function of magnitude, to produce the equivalent of an N(0,1) measure, i.e. a normalised Gaussian of zero-mean and unit variance. Objects lying within 2-3 σ are generally flagged as stellar images, those below 3σ (i.e. sharper) as noise-like, and those above 2-3 σ (i.e. more diffuse) as non-stellar.

A by-product of the curve-of-growth analysis is the estimate of the average PSF aperture correction for each detector.

2.15 Photometric Zeropoint

For the purposes of quality control (e.g. sky transparency and system performance) a primary photometric zeropoint will be determined for each observation by direct comparison of instrumental magnitudes with the magnitudes of 2MASS stars. An alternative cross-check on the photometric calibration will be applied retrospectively given a complete night of observations including regular exposures in VISTA photometric standard fields.

The internal gain-correction, applied at the flat-fielding stage, should place all the detectors on a common zeropoint system (at least to first order i.e. ignoring colour equation variations between the detectors), and given a stable instrumental setup, the apparent variation of zeropoint then directly measures the change in "extinction"

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 obigi	Date:	2006-12-12
System		Page:	23 of 145

without the need to rely solely on extensive standard field coverage over a range in airmass. Therefore for any given observation of a star in a particular passband:

$$m^{cal} = m^{inst} + ZP - \kappa \ (X - 1) = m^{std} + ce^{std} + \varepsilon$$
(2-34)

where ZP is the zeropoint in that passband (i.e. the magnitude at airmass unity which gives 1 count/second at the detector), m^{cal} is the calibrated instrumental magnitude, m^{inst} is the measured instrumental magnitude (-2.5 × log₁₀[counts/sec]), κ is the extinction coefficient, X is the airmass of the observation, ce^{std} is the colour term to convert to the instrumental system, and ε is an error term. This assumes that the second-order extinction term and colour-dependency of κ are both negligible. By robustly averaging the zeropoints for all the matching stars on the frame an overall zeropoint for the observation can be obtained.

Typically, the zeropoint of the instrument + telescope system should be stable throughout the night. Long-term decreases in the sensitivity of the instrument, and hence a decreasing *ZP*, could be caused by for example the accumulation of dust on the primary mirror.

On photometric nights the extinction coefficient κ should be constant in each passband. The extinction κ can be monitored through each night either by assuming the true instrumental zeropoint only varies slowly as a function of time (and using the individual 2MASS calibrations to monitor it) or by making measurements over a range of airmass.

2.16 Illumination Correction

The two methods of determination of illumination correction differ in that the first described below requires either a rich standard star field or a series of fields with known photometry, but the second can be used before such information is available.

2.16.1 Standard Star Fields

Errors in the large scale structure of the illumination of the flat fields used in signature removal can cause position dependent systematic errors in photometry. This can be a result of a varying scattered light profile between twilight (nominally when the flat field exposures would have been made) and the time when the observation was done. We can map this out by first dividing an observation of a rich photometric standard field into cells or by dividing a series of calibrator fields from, for example, 2MASS into cells. For each cell we define a median zero point of all the stars in that cell:

$$zp_{j} = \left\langle m^{cal} - m^{inst} \right\rangle$$
 (2-35)

(It is safe to ignore the extinction term for this exercise.) The illumination correction is then defined for each cell as:

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	24 of 145

$$ic_{j} = \langle zp \rangle - zp_{j}$$
 (2-36)

where $\langle zp \rangle$ is the median value of zp_j over all the cells. This is defined such that a star in the *j*th cell is calibrated by:

$$m^{cal} = m^{inst} + ZP - \kappa (X-1) - ic_j$$
 (2-37)

2.16.2 Mesostep Analysis

We assume that the spatial sensitivity of each detector can be approximated by a polynomial surface, i.e. a magnitude offset as a function of (x, y) measured from the centre of the detector, e.g.

$$ZP(x,y) = \sum_{hk} a_{hk} x^h y^k$$
(2-38)

For example, in quadratic form, at positions *i* and *j*:

$$ZP(x_i, y_i) = a_{00} + a_{10}x_i + a_{01}y_i + a_{20}x_i^2 + a_{11}x_iy_i + a_{02}y_i^2$$
(2-39)

$$ZP(x_j, y_j) = a_{00} + a_{10}x_j + a_{01}y_j + a_{20}x_j^2 + a_{11}x_jy_j + a_{02}y_j^2$$
(2-40)

The difference in sensitivity/zeropoint between two positions *i* and *j* is then:

$$\Delta ZP(x_i, x_j, y_i y_j) = a_{10}(x_i - x_j) + (a_{01}(y_i - y_j) + a_{20}(x_i^2 - x_j^2) + a_{11}(x_i y_i - x_j y_j) + a_{02}(y_i^2 - y_j^2)$$
(2-41)

If we make two observations of the same star at offset positions $i(x_i, y_i)$ and $j(x_j, y_j)$, we sample this function such that the difference in magnitude measured is Δm_{ii} then:

$$\Delta m_{ij} = \Delta ZP(x_i, x_j, y_i y_j)$$
(2-42)

In the simplest case, observing the same star in a number of different places would allow one to measure the Δm_{ij} as a function of (x_i, y_i) and (x_j, y_j) . One could then fit a polynomial using least-squares and solve for the a_{hk} . The multiple observations of multiple stars in a grid across the array ensure we can solve for the polynomial coefficients accurately.

3 Functional Description

Science data from VIRCAM is processed by a single recipe, namely vircam_jitter_microstep_process. Various other recipes are provided to generate the calibration data essential for instrumental-signature removal. A variation of the science recipe, vircam_standard_process, is used on observations of standard fields (which will contain many standard stars) to produce a photometric zeropoint. The recipes will work for both the Paranal and Garching pipeline environments, but it is expected that higher-quality results will be obtained at Garching where complete nights of data will be analysed.

An overview of the whole VIRCAM pipeline is illustrated in Figure 3-1.

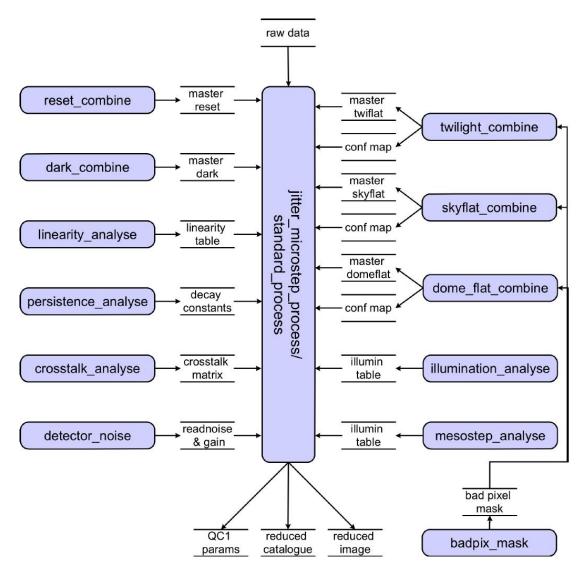

Figure 3-1 Relationship between recipes, calibration data and data products.

There will initially be no calibration data, and so the pipeline must be "bootstrapped" by executing the recipes in the order shown in Figure 3-2. After this, there should be the minimum set of library calibration data to run the whole pipeline in production mode.

4 Instrument Data Description

There is only one data format, used in both IMAGING and HOWFS modes; but note, however, HOWFS data is analysed in real time on the instrument workstation and is not passed to the pipeline, and so will not be further considered here. Data frames will be in ESO modified standard FITS format [RD 5], the ESO modifications being limited to the hierarchical header proposal, and compliant with DICB standards [AD5]. The headers are also compliant with the final World Coordinate System (WCS) specification [RD 8]. Data from the full set of chips are stored in Multi Extension Format (MEF) as 32-bit signed integers [RD 6]. Offset 16-bit format is not used because data will be co-added in the data acquisition system before output. Though not a requirement, the integer format enables the use of highly efficient lossless compression.

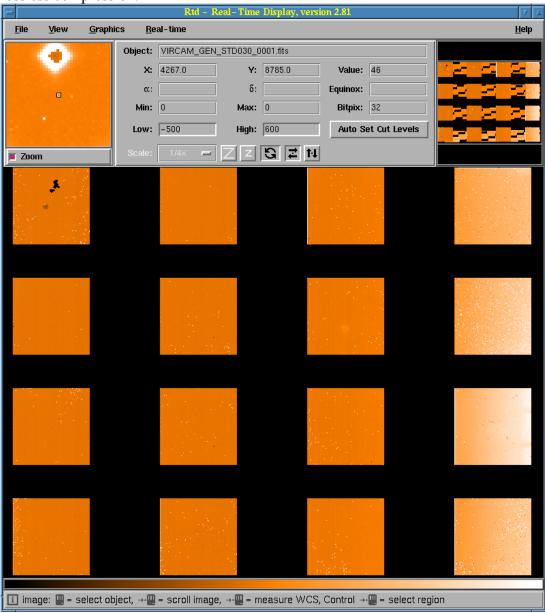

Figure 4-1 A VIRCAM engineering readout shown displayed in the ESO-VLT Real-Time Display Tool

Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	38 of 145

Raw VIRCAM data will contain headers from ESO standard DPR, OBS, TPL dictionaries and at least the following set of data dictionaries (and see [RD 2]):

- ESO-VLT-DIC.VIRCAM_CFG
- ESO-VLT-DIC.VIRCAM_HOWFS
- ESO-VLT-DIC.VIRCAM ICS
- ESO-VLT-DIC.VIRCAM OS
- ESO-VLT-DIC.VTCS
- ESO-VLT-DIC.IRACE

A full simulated FITS header is illustrated in the appendix (section 11).

A full 256MByte VIRCAM exposure simulation is shown in Figure 4-1, and two examples shown organised by GASGANO in Figure 4-2 demonstrate the compliance of the data format design with ESO data-interface standards.

The flow from raw data types and the templates which generate them, through the processing recipes and required calibration data, to final data products is shown in the data-processing table (Table 4-1, below).

5 DRL Data Structures

5.1 Introduction to Data Products

The main pipeline products will be images stored as image extensions in multiextension FITS files, and derived parameters from the processing stored as FITS keyword/value pairs in the appropriate FITS header units.

All science frames will be corrected for the standard instrumental signatures such as flat fielding and dark current, and for other possible electronic artefacts, such as crosstalk, persistence and reset anomalies. In addition all pawprint images will be astrometrically and photometrically calibrated, with the calibration information being stored as FITS header keywords in each image extension. A header keyword that associates each FITS image file with its confidence map file will also be included in the primary header unit. This keyword is in the form of a timestamp and is stored in the key ESO DRS VIR_TIME.

The pipeline will also generate detected object catalogues for each science image which will be used in deriving much of the QC and calibration information. These will be stored as multi-extension FITS binary tables with a copy of the FITS header information from the FITS image files and a one-to-one correspondence of table and image extensions. Derived QC and calibration information will be added to these FITS catalogue files and also propagated to the FITS image files as described in [AD5]. In general the pipeline products fall into one of the following classes:

Science Images:

- images of single exposures
- pawprints arising from combining (stacking) jitter and microstep sequences

Object Catalogues:

lists of detected parameterised objects for each science image (see 5.12)

Derived On-sky Calibration Information:

- Photometric zero points
- WCS coefficients
- other QC parameters (see Appendix for full specification)

Confidence Maps:

- Bad pixel masks derived from dome flat sequences
- Single image confidence maps derived from twilight flats and bad pixel masks
- Stacked/interleaved image confidence maps which also include effective exposure maps

Calibration Maps:

- Master combined dark frames
- Master combined flat field images
- Master eigen-fringe frames

Other Calibration Products:

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	44 of 145

- Non-linearity coefficients for each data channel of each detector
- Persistence coefficients for each detector
- A 256x256 crosstalk matrix for the entire focal plane
- Illumination correction tables

Products from these lists that require extra explanation are discussed in the rest of this chapter. Below is a table with the data products and their PRO.CATG and DO.CATG keyword values (where values can be used as input and output the values of these keywords are the same).

Product	PRO.CATG/DO.CATG		
Master reset frame products			
Master reset frame	MASTER RESET

Output interleaved images	INTERLEAVED IMAGE
Output stacked image	JITTERED IMAGE
Output interleaved and stacked image	INTERLEAVED STACKED IMAGE
Output stacked/interleaved confidence map	CONFIDENCE MAP
Output object catalogues	OBJECT CATALOGUE

 Table 5-1 DO and PRO categories for data products

It is imperative that a recipe continue on as best it can until all frames in the input frameset are processed. Thus in the event of some sort of failure, the recipe may have to generate '*dummy*' data products. These are images, tables etc. that are written to a FITS extension in the place of the data product that you would have normally expected from the given recipe. Dummy products are necessary in the event that you are processing many/all of the available extensions in one go. The dummy frames hold a position in the output data product FITS file where the real product should have gone, had there not been a failure. The types of failure that will generate dummy products are: the headers of the input frames indicate that detector was dead during the observation; an inability to load the necessary FITS image extensions for a particular detector; missing header information etc. A dummy product will be flagged with the Boolean header item ESO DRS IMADUMMY.

5.2 Channel Table

Each VIRCAM detector will be split into 16 different data channels, each with its own electronics. This means that some reduction tasks will rely on knowing the location and readout timing information for each data channel. The location and linearity information will be provided by the 'channel table'. The information will be stored in a multi-extension FITS file with each extension being a FITS binary table (one for each detector). Each of the tables will contain the columns listed in below (although perhaps not in this order). The extension name should match the extension names for the input images. It is worth remembering here that there is no zeroth order coefficient, so the number of coefficient columns is the same as the polynomial order.

Column	Name	Туре	Units	Description
1	channum	int		Number of the data channel, which is an integer from 1-16. This is a unique ID for the data channel in the context of the detector of which it is a part.
2	ixmin	int	pixels	The X coordinate of the lower left corner of the data channel
3	ixmax	int	pixels	The X coordinate of the upper right corner of the data channel
4	iymin	int	pixels	The Y coordinate of the lower left corner of the data channel
5	iymax	int	pixels	The Y coordinate of the upper right corner of the data channel

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	46 of 145

6	dcrpix1	int	pixels	The X coordinate of the location within the data channel where the first pixel is
		•		read out.
7	dcrpix2	int	pixels	The Y coordinate of the location with the data channel where the first pixel is read out.
8	dcd1_1	int		Can take the values (-1,0,1). Gives the partial derivative of the fast readout axis with respect to the X axis.
9	dcd1_2	int		Can take the values (-1,0,1). Gives the partial derivative of the fast readout axis with respect to the Y axis.
10	dcd2_1	int		Can take the values (-1,0,1). Gives the partial derivative of the slow readout axis with respect to the X axis.
11	dcd2_2	int		Can take the values (-1,0,1). Gives the partial derivative of the slow readout axis to the Y axis.
12	qualfit	double		The quality of the linearity fit for this channel
13	lin_10000	double		The percentage non-linearity for the current channel at a level of 10000 ADU
14	norder	int		The order of the polynomial used in the fit.
15	coeff_1	double		The first coefficient in the fit. This must be set to 1 always
•				
. .				
14+n	coeff_n	double		The nth order coefficient, where n=norder

5.3 Bad Pixel Mask

As we mentioned in section 2.13 on confidence maps, it is essential for many of the operations of the pipeline to know exactly which pixels in each image are always likely to be bad. This is done initially using a bad pixel mask. This will take the form of a FITS container file with an image extension of type byte for each detector. The values in the data array will be set to one for bad pixels and zero for good ones.

5.4 Confidence Maps

Confidence maps combine bad pixel information with variance information in composite images, as described fully in 2.13. The maps are kept as FITS MEF files in

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 obigi	Date:	2006-12-12
System		Page:	47 of 145

short integer format in which zero equates to completely bad pixel and 100 to completely good pixel.

5.5 Dark Current Image

Dark current is calculated by a looking at the time rate of change of the data in a series of dark frames taken with a variety of exposure times on a pixel by pixel basis. The result is a map with an estimate of the dark current (in ADU/sec) for each pixel.

5.6 Crosstalk Matrix

Detector crosstalk is described in section 2.9. In order to correct for this effect we need a factor that defines the effect of one channel on a second one, i.e. a crosstalk matrix. This will be generated on an occasional basis and will be stored in the form of a FITS binary table with the following columns:

Column	Name	Туре	Units	Description
1	source	int		The channel index of the crosstalk
				source
2	victim	int		The channel index of the victim of the
				crosstalk
3	coef	float		The scaling factor required to remove
				the source crosstalk from the victim.

The information in this table will be used by the crosstalk correction routine in conjunction with the channel table (5.1).

5.7 Illumination Correction Table

The effect of large scale background variation in the flat field images (usually due to scattered light) are described in section 2.16. An illumination correction table is generated by dividing the image plane into a number of boxes, using the systematic photometric zeropoint changes across the image to define the correction for each box. This is used to correct the instrumental magnitudes of subsequent observations for positional biases. This will be stored in the form of a series of binary FITS tables (one per detector) in a single MEF container with the following columns:

Column	Name	Туре	Units	Description	
1	xmin	int	pixels	The X position of lower left corner of the box	
2	xmax	int	pixels	The X position of upper right corner of the box	
3	ymin	int	pixels	The Y position of lower left corner of the box	
4	ymax	int	pixels	The Y position of upper right corner of the box	
5	illcor	float	mag	The illumination correction for the box	

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	48 of 145

5.8 Difference/Ratio Images

Some of the recipes will attempt to monitor performance of the detectors by comparing current images with library versions (e.g. dark frames). For additive effects like reset and dark current this can most easily be achieved with a difference image. This is simply the difference of two images in the sense of the master subtracted from the current image. Similarly for multiplicative effects like flat fielding this is most easily achieved with a ratio image which is the current image divided into the master image.

5.9 Difference/Ratio Image Statistics Tables

For recipes that monitor detector performance in particular, it is often worthwhile to keep statistical information on difference/ratio images. This is because frames are often compared to library frame either by forming a difference or a ratio and the statistics in cells or subsections across the output image can be a useful diagnostic to detector performance. A difference/ratio image statistics table will be a FITS table with the following columns defined:

Column	Name	Туре	Units	Description
1	xmin	int	pixels	The X position of lower left corner of the cell
2	xmax	int	pixels	The X position of upper right corner of the cell
3	ymin	int	pixels	The Y position of lower left corner of the cell
4	ymax	int	pixels	The Y position of upper right corner of the cell
5	chan	int		The data channel to which this cell belongs. This is only useful if the whole cell fits into a data channel.
5	mean	float	adu	The mean value in the cell
6	median	float	adu	The median value in the cell
7	variance	float	adu	The variance of the values in the cell
8	mad	float	adu	The median absolute deviation from the median of the values in the cell.

5.10 Persistence Mask Table

Dealing with image persistence properly requires knowledge of observations that were done previous to the current one. In the on-line pipeline this can be approximately accomplished by processing the observations from a particular template with respect to the times that they were done. This sort of information then can be used in conjunction with the persistence decay time constant and the end time of the current exposure to decide which frames will have affected the current image and how to scale them to correct the problem. The columns for the persistence mask table are:

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	49 of 145

Column	Name	Туре	Units	Description	
1	srcimage	char		The name of the source image	
2	srctime	int	seconds	The end time of the source observation in seconds from 1 Jan 2000.	

5.11 Standards Table

During the course of the pipeline reductions it will be necessary to extract information from standard astrometric and photometric catalogues. The results of this extraction will be in an Extracted Standards Table and will contain the following columns:

Column	Name	Туре	Units	Description
1	xpredict	float	pixels	The X position of the matching standard as predicted from the image WCS and the object's equatorial coordinates.
2	ypredict	float	pixels	The Y position of the matching standard as predicted from the image WCS and the object's equatorial coordinates.
3	RA	float	degrees	The standard's RA
4	Dec	float	degrees	The standard's Dec
5 – n	mags	float	mags	Any photometric information that might exist in the standard star catalogue

5.12 Object Catalogues

The derived object catalogues are stored in multi-extension FITS files as binary tables, one for each image extension. Each detected object has an attached set of descriptors, forming the columns of the binary table, and summarising derived position, shape and intensity information (see section 2.14 for more details).

The following columns are present:

Column	Name	Description
1	Sequence number	Running number for ease of reference, in strict order
		of image detections
2	Isophotal_flux	Standard definition of summed flux within detection
		isophote.
3	X_coordinate	The <i>x</i> , <i>y</i> coordinates and errors with $(1, 1)$ defined to be
4	X_coordinate_err	the centre of the first active pixel in the image array.
5	Y_coordinate	See 2.14.2.
6	Y_coorindate_err	
7	Gaussian_sigma	Second moment parameters. See 2.14.2

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	50 of 145

8	Ellipticity	
9	Position angle	
10	Areal 1 profile	The number of pixels above a series of threshold levels,
11	Areal 2 profile	relative to local sky. The levels are set at T, 2T, 4T, 8T,
12	Areal 3 profile	16T, 32T, 64T and 128T where T is the analysis
13	Areal 4 profile	threshold
14	Areal 5 profile	
15	Areal 6 profile	
16	Areal 7 profile	
17	Areal 8 profile	
18	Peak height	Peak intensity and its error in ADU relative to local
19	Peak height err	value of sky
20	Aper flux 1	Flux and error within a specified radius aperture,
21	Aper flux 1 err	typically set so that $R_{aperture} = \langle FHWM \rangle$ where the
22	Aper_flux_2	quantity in angle brackets is the mean FWHM of all
23	Aper_flux_2_err	stellar images. This is also known as the "core radius".
24	Aper_flux_3	
25	Aper_flux_3_err	The apertures here correspond to $(0.5, 1/\sqrt{2}, 1, \sqrt{2}, 2, 1)$
26	Aper_flux_4	$2\sqrt{2}$, 4, 5, 6, 7, 8, 10, and 12) times the core radius.
27	Aper_flux_4_err	
28	Aper_flux_5	
29	Aper_flux_5_err	
30	Aper_flux_6	
31	Aper_flux_6_err	
32	Aper_flux_7	
33	Aper_flux_7_err	
34	Aper_flux_8	
35	Aper_flux_8_err	
36	Aper_flux_9	
37	Aper_flux_9_err	
38	Aper_flux_10	
39	Aper_flux_10_err	
40	Aper_flux_11	
41	Aper_flux_11_err	
42	Aper_flux_12	
43	Aper_flux_12_err	
44	Aper_flux_13	
45	Aper_flux_13_err	
46	Petr_radius	Petrosian radius r_p in pixels as defined in Yasuda, et al.
		2001, AJ, 112, 1104.
47	Kron radius	Kron radius r_k in pixels as defined by Bertin and
		Arnouts 1996, A & A Supp, 117, 393.
48	Hall radius	
-0		Hall radius r_h in pixels as defined by Hall and Mackay
40		1984, MNRAS, 210, 979.
49	Petr_flux	

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar j 2 oorgi	Date:	2006-12-12
System		Page:	51 of 145

50	Petr_flux_err	Petrosian flux and error to $2r_p$	
51	Kron flux	Kron flux and error to $2r_k$	
52	Kron flux err	K K	
53	Hall flux	Hall flux and error to $5r_h$. Alternative total flux.	
54	Hall flux err	n	
55	Error_bit_flag	Bit pattern listing various processing error flags.	
		Currently this is the number of bad pixels included in the aperture flux	
56	Sky level	Local interpolated sky level from background tracker	
57	Sky_rms	Local estimate of variation in sky level around images	
58	Parent or child	Flag for parent or part of de-blended deconstruct.	
58 59	RA		
<u> </u>		RA and Dec of each object in degrees. These are added	
	Dec	during WCS refinement	
61	Classification	simple flag indicating most probably classification for	
		object:	
		-9: Saturated	
		-2: Object is compact (maybe stellar)	
		-1: Object is stellar	
		0: Object is noise	
		1: Object is non-stellar	
	Statistic	an equivalent $N(0,1)$ measure of how stellar-like an	
		image is. It is used in deriving the classification (25) in	
		a "necessary but not sufficient" sense. This statistic is	
		computed from a discrete curve-of-growth analysis	
		from the peak and aperture fluxes and also factors in	
		ellipticity information. The stellar locus is used to	
		define the "mean" and "sigma" as a function of	
		magnitude such that the "statistic" can be normalised to	
ļ		an approximate N(0,1) distribution.	
63-80	blank		

5.13 Matched Standards Table

When doing astrometric and/or photometric reduction it is necessary to match astronomical objects that appear on an image with objects from a standard catalogue. The output from such a matching algorithm is called a Matched Standards Table and will contain all the columns from both input tables (cf. 5.11 and 5.12).

5.14 Readnoise/Gain File

This is a multi-extension FITS file where each extension is a null FITS image. Each extension will have at least the following keywords in its header:

Keyword	Туре	Description
chipname	char	The name of the chip to for the current noise values
readnois	float	The readout noise of the chip in units of electrons.
gain	float	The gain of the chip in units of electrons per ADU

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	52 of 145

5.15 Photometric Calibration Table

This is a table used to define the transformation from instrumental to standard magnitudes.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	53 of 145

Column	Name	Туре	Description
1	filter	char	The name of the filter
2	extinction	float	The extinction coefficient for airmass of unity for the
			given filter.
3	offset	float	A pedestal value to be added to the instrumental
			magnitude once the colour equation has been applied.
4	columns	char	The standard magnitude columns from the matched
			standards catalogue to be used. This is the names of the
			columns separated by a comma.
5	coleq	char	The colour equation coefficients. There should be one
			coefficient for each of the columns mentioned in the
			columns field. This should be formatted as a series of
			floating point numbers separated by commas.

6 DRL Functions

In what follows we describe the low level functions that will be driven by the VIRCAM pipeline. The parameter list describes the full API for each function. Many of the functions make use of the following structures:

- **vir_fits:** This is a convenience structure that binds the **cpl_image** object for a particular image with the name of the originating FITS file, the image extension number, the primary header propertylist and the propertylist for the extension header.
- **vir_tfits:** In a similar way, functions that get information from an existing FITS table will have parameters declared **vir_tfits**. This wraps a **cpl_table** object with the same ancillary information as above for **vir_fits**.
- **vir_mask:** This is provided as a means to load and manipulate stand-alone bad pixel masks. These can come from a bad pixel mask FITS file or a confidence map.

A feature of the DRL functions is an inherited status parameter. This is always the last in the parameter list and it is also the return value from each function. Each function will test the status value as its first action and return immediately if the status is bad. The error messages will be passed through the CPL error structure and hence information on the origin and cause of any error will not be lost by using inherited status.

CPL currently has no facility for generating or manipulating the information required for a full World Coordinate System. As this is a vital piece of information for any astronomical observation we have sought to rectify this situation by importing a WCS package into the VIRCAM software. This package is called **wcslib** and was written by Mark Calabretta, who is one of the leading authorities on the representation of world coordinate systems in astronomy. The VIRCAM pipeline accesses the functions in **wcslib** through a simple set of wrapper routines. These were written in anticipation that CPL itself would eventually provide this kind of functionality. When it does, then just the internals of the wrapper routines will need rewriting.

In this chapter we have simplified the descriptions of the functions by omitting both very obvious and repetitive features. A list of these shortcuts is included below.

- We have not enumerated very obvious keywords in the input or output header lists. These include things like the data array size, data type and data dimensionality.
- Inherited bad status will cause each function to return immediately without updating the CPL error message.
- A fatal error condition in a function will cause an appropriate CPL error message to be set and will cause the function to return to the calling routine immediately where the pipeline can take the necessary steps to terminate gracefully. We do not include segmentation violations, arithmetic exceptions and the like in the definition of a fatal error.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	55 of 145

- Very obvious error conditions such as corrupted input files, running out of disc space, etc have been omitted for brevity.
- Any function parameters that refer to image data will have the expected data type in square brackets next to the parameter name.

6.1 vircam_crosstalk

6.1.1 General

Name:

vircam_crosstalk

Purpose:

Remove electronic crosstalk from an image

General Description

Electrical crosstalk is removed from each data channel in the input images by means of a crosstalk matrix (see section 5.6). The latter consists of factors by which the data from one channel affects another. The applicability is to be decided during laboratory and on-sky tests.

Mathematical Description:

See section 2.9 for a full mathematic description of crosstalk removal.

6.1.2 Function Parameters

None

6.1.3 Input Images and Required FITS Header Information.

infiles (float)

The input science container-file to be corrected; this must contain a full list of all the source and victim images.

6.1.4 Input Tables

xtable

The crosstalk matrix (see 5.6)

chantab

The channel table (see 5.2)

6.1.5 Output Images

outfile (float)

The output science image; if this is the same as the value for **infile** or is blank, then the output will overwrite the input.

keyword	type	description
DRS XTCOR	char	The name of crosstalk matrix table used

6.1.6 Output Tables

None

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	56 of 145

6.1.7 Other Output

None

6.1.8 QC1 Outputs

None

6.1.9 Quality Assessment

Crosstalk artefacts are removed to with the expected sky noise

6.1.10 Error Conditions

- There are no fatal error conditions.
- There are no non-fatal error conditions

6.2 vircam_darkcor

6.2.1 General

Name:

vircam_darkcor

Purpose:

Remove reset anomaly and dark current using a library mean dark frame of matching exposure/integration time if available.

General Description

The data array of the input dark frame is multiplied by a predetermined factor such that it matches the scale of the reset anomaly in the target object frame. The scaled dark frame is then subtracted from the target frame.

Mathematical Description:

 $I_i^{out} = I_i^{in} - kD_i$

where I is the input data, D is the mean dark frame data and k is the scaling factor.

6.2.2 Function Parameters

vir_fits *infile [float]

The input science image to be corrected. This will be overwritten by the corrected image

vir_fits *darksrc [float]

The input mean dark image

float darkscl

An input scaling factor. This corresponds to the value of k in the mathematical description above.

int *status

Input/output status from function.

6.2.3 Required Input FITS Header Information

None

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	57 of 145

6.2.4 Output FITS Header Information

The following will be appended to the extension header for **infile**.

keyword	type	description
DRS DARKCOR	char	The name of the master dark file specified in darksrc
DRS DARKSCL	float	The scale factor used in the subtraction

6.2.5 QC1 Outputs

None

6.2.6 Quality Assessment

Reset anomaly ramp removed

6.2.7 Fatal Error Conditions

- Mismatched data array dimensionality between the input images
- The image data fails to load

6.2.8 Non-Fatal Error Conditions

None

6.3 vircam_defringe

6.3.1 General

Name:

vircam_defringe

Purpose:

Remove fringe patterns from an image using a mean fringe frame and a scaling algorithm

General Description

Large scale variations are removed from the input frame by dividing the image into squares over which a background median can be determined and then constructing an interpolated background correction. The fringe image is scaled by a value and subtracted from the input image. Statistics of the image show whether the scale factor used was too high or too low. The scale factor is adjusted and the fit is attempted again. This is repeated to convergence. Once convergence is achieved, then the fringes are removed with the correct scale factor. The background map variation is then added back in.

Mathematical Description:

 $I_i = I_i - k * Fr_i$ where *I* is the input image data, *k* is the fringe scaling factor and *Fr* is the fringe data. For a full description of how the scale factor and the fringe data are computed see section 2.7.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	58 of 145

6.3.2 Function Parameters

vir_fits ****infiles** [float]

The input science images to be corrected. These gets overwritten by the corrected images

int **nfiles**

The number of science images in the infiles list

vir_fits ****fringes** [float]

The list of fringe images

int **nfringes**

The number of fringe images in the input list

vir_mask *mask

The input bad pixel mask

int nbsize

The size of the cell for background modelling

int *status

Input/output status from function

6.3.3 Required Input FITS Header Information

None

6.3.4 Output FITS Header Information

The following will be appended to the extension header for each input image

keyword	type	description
DRS FRINGEn	char	The name of the fringe file used in the nth defringing pass
DRS FRNGSCn	float	The scale factor for the nth defringing pass.

6.3.5 QC1 Outputs

FRINGE_RATIO

6.3.6 Quality Assessment

The FRINGE_RATIO indicates that the background variation has decreased significantly $% \mathcal{A} = \mathcal{A} = \mathcal{A} + \mathcal{A}$

6.3.7 Fatal Error Conditions

None

6.3.8 Non-Fatal Error Conditions

None

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	59 of 145

6.4 vircam_destripe

6.4.1 General

Name:

vircam_destripe

Purpose:

Remove background stripes

General Description

The stripes in the background of an image are modelled by doing a block median of each row. This gives a 1d profile which is normalised to zero median. Each point on the profile is subtracted from a row in the input image. Bad pixels or object pixels can be removed with a bad pixel mask or a confidence map.

Mathematical Description:

None

6.4.2 Function Parameters

vir_fits *in [float]

The input science image to be corrected. This gets overwritten by the corrected image

vir_mask ***inbpm**

The input mask

int *status

Input/output status from function

6.4.3 Required Input FITS Header Information

None

6.4.4 Output FITS Header Information

The following will be appended to the extension header for in.

keyword	type	description
DRS STRIPECOR	bool	Set if the stripe correction has been done
DRS STRIPERMS	float	The RMS of the stripe pattern removed from the image

6.4.5 QC1 Outputs

None

6.4.6 Quality Assessment

None

6.4.7 Fatal Error Conditions

• The image data fails to load

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	60 of 145

6.4.8 Non-Fatal Error Conditions

None

6.5 vircam_flatcor

6.5.1 General

Name:

vircam_flatcor

Purpose:

Remove large and small scale gain variations by dividing science frames by a mean flat field frame.

General Description

The data array of the input image is divided by that from a mean flat field image. The mean flat field should have been normalised in the manner described in section 2.3. This ensures that during this reduction step we perform both for the flat field correction and the detector gain correction.

Mathematical Description:

 $I_i^{\mathit{out}} = I_i^{\mathit{in}} \, / \, F_i$

where I is the input data and F is the mean flat field data.

6.5.2 Function Parameters

vir_fits ***infile** [float]

The input science image to be corrected. This gets overwritten by the corrected image

vir_fits *flatsrc [float]

The input mean flat field image

int *status

Input/output status from function

6.5.3 Required Input FITS Header Information

None

6.5.4 Output FITS Header Information

The following will be appended to the extension header for **infile**.

keyword	type	description
DRS FLATCOR	char	The name of the flat field image specified in flatsrc

6.5.5 QC1 Outputs

None

6.5.6 Quality Assessment

Robust estimates of the background of each detector image agree c.f. to expected sky noise.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	61 of 145

6.5.7 Fatal Error Conditions

- Mismatched data array dimensionality between the input images
- The image data fails to load

6.5.8 Non-Fatal Error Conditions

None

6.6 vircam_genlincur

6.6.1 General

Name:

vircam_genlincur

Purpose:

Generate linearity coefficients given a list of dome flat field exposures.

General Description:

A series of dark corrected exposures of a stable dome light source with a range of exposure times should be given. From the known readout, reset, dit-delay and exposure times a timing map is constructed for each pixel according to the algorithm outlined in section 2.2.2. The results are written to a new channel table.

Mathematical Description:

This function implements the mathematical description in section 2.2.2

6.6.2 Function Parameters

vir_fits **imlist [float]

The list of input dark corrected dome flat images

int nimages

The number of images in the list

vir_tfits *chantab

The input channel table for the detector represented in the input image list. This is described in section 5.2.

int norder

The order of the polynomial to use in the expansion; note that because the zeroth term is defined to be zero, then the number of coefficients this routine will derive is the same as the polynomial order

int kconst

A flag, which, if set, signals that the value of k defined in section 2.2.2 is constant for all pixels in a given image

unsigned char *bpm

A bad pixel mask.

cpl_table *lchantab

The output channel table.

int *status

Input/output status from function

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	62 of 145

6.6.3 QC1 Outputs

None

6.6.4 Required Input FITS Header Information

The following values need to be included in the extension headers of each of the files in **imlist**.

keyword	type	description
EXPTIME	float	The exposure time for the image
ESO DET MINDIT	float	The minimum DIT time
ESO DET DITDELAY	float	A delay between the reset and the first read

6.6.5 Output FITS Header Information

None

6.6.6 Quality Assessment

The value of the **qualfit** and **lin_10000** columns are reasonable for all channels.

6.6.7 Fatal Error Conditions

- Invalid channel table.
- Inability to map the data arrays of input images

6.6.8 Non-Fatal Error Conditions

• Failed fit for a channel

6.7 vircam_getstds

6.7.1 General

Name:

vircam_getstds

Purpose:

Given an input FITS header, extract a list of standard stars from a catalogue that should appear on the relevant image.

General Description:

The header of an input image is parsed to locate and read the standard WCS FITS header keywords. The WCS is used to define the coverage of the image in equatorial coordinates. The coverage is used to select objects from the 2MASS point source catalogue. (The catalogue is expected to be made available in FITS table form.) Once the stars have been selected the information about them is written to an extracted standards table (5.11) along with their expected x, y positions based on the input WCS.

Mathematical Description:

N/A

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Listury Design	Date:	2006-12-12
System		Page:	63 of 145

6.7.2 Function Parameters

cpl_propertylist *plist

The propertylist representing the FITS header of an input image. This header must have all of the keywords listed in the FITS header section below.

int cache

A flag, which, if set, indicates that a local cache should be set up to store catalogues that you have extracted. If used, this can significantly reduce the amount of searching that is required of the whole 2MASS catalogue and hence cut down the amount of time this routine takes. This is especially important when many exposures are being done in the same part of the sky.

char *path

The full path to the directory where the 2MASS FITS tables are held.

cpl_table *index

An index table for the catalogue FITS files – this parameter must be NULL on entry for the first time this routine is called and must be deleted explicitly after the last time this routine is called.

cpl_table ****stds**

The output table of standards

int *status

Input/output status from function

6.7.3 Required Input FITS Header Information

The following must be available in the input propertylist **plist**.

keyword	type	description
CRPIX1	double	All of the standard FITS WCS keywords that are relevant for the
CRPIX2	double	projection model to be used with VIRCAM (nominally ZPN).
CTYPE1	char	See [RD 8] for more specific information
CTYPE2	char	
CRVAL1	double	
CRVAL2	double	
CD1_1	double	
CD1_2	double	
CD2_1	double	
CD2_2	double	
PV2_1	double	
PV2_3	double	

6.7.4 Output FITS Header Information

None

6.7.5 QC1 Outputs

None

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	64 of 145

6.7.6 Quality Assessment

N/A

6.7.7 Fatal Error Conditions

- Inability to read the index table.
- Inability to read the catalogue tables.

6.7.8 Non-Fatal Error Conditions

• No objects found in the catalogue

6.8 vircam_illum

6.8.1 General

Name:

vircam_illum

Purpose:

Work out the spatial corrections in the photometric zero point.

General Description:

This function takes a table of photometric standards and a table of objects extracted from a list of images. The objects in both of the input tables are matched up. The pixel space of the original image is divided up into cells of **nbsize** pixels on a side. The mean zero point for each cell is calculated. Next the ensemble-mean zero point is calculated for all the cells. The illumination correction is then defined for each cell as the residual zero point from that mean. The sense of the illumination correction for a cell is such that it must be subtracted from the mean frame zero point for objects in that cell.

Mathematical Description:

This function implements the mathematical description in section 2.16

6.8.2 Function Parameters

vir fits **images

The input list of images

cpl_table ****mstds**

The list of matched standards tables (section 5.13), one for each input image cpl_propertylist ****pl**

An array of propertylists representing the headers of the object catalogues that were derived from the input images.

int nimages

The number of images, matched standards catalogues and propertylists. char ***filt**

The name of the filter for these observations.

cpl_table *phottab

The photometric calibration table (section 5.15)

int **nbsize**

The size of the side of a cell

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 obigi	Date:	2006-12-12
System		Page:	65 of 145

cpl_table *illcor

The illumination correction table (section 5.7)

float ***illcor_rms**

The RMS of the illumination correction map

int *status

The input/output function status

6.8.3 Required FITS Header Information

The following information is required in the extension header of the catalogues (see the parameter **pl**)

keyword	type	description
APCOR3	float	The aperture correction for aperture 3 as calculated
		by vircam_imcore
ESO QC SATURATION	float	The saturation level in counts

The following information is required from the primary header of the images

keyword	type	description
ESO TEL AIRM START	float	The airmass at the start of the observation.
EXPTIME	float	The exposure time in seconds

6.8.4 Output FITS Header Information

None

6.8.5 QC1 Outputs

ILLUMCOR_RMS

6.8.6 Quality Assessment

Applying the correction table to the input file should result in a magnitude zero point with an RMS consistent with the mean RMS of the source photometric catalogue. This can be seen with the keyword DRS MAGZERR which is generated by **vircam_photcal** (6.18).

6.8.7 Fatal Error Conditions

- Photometric calibration table is incomplete
- No input images
- No rows in matched standards catalogue
- Missing header information in standards catalogue or image

6.8.8 Non-Fatal Error conditions

• No zeropoints can be calculated

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	66 of 145

6.9 vircam_imcombine

6.9.1 General

Name:

vircam_imcombine

Purpose:

Combine a list of images into an output image. Allow for x, y shifting, intensity biasing, intensity scaling, image weighting and bad pixel rejection.

General Description:

A list of images is combined to form an output image. The output image can be either a mean of the input pixels or a median. The images can have the following done to them before combination:

- the input data values for a given output pixel can be scaled by a preset amount for each input image
- the input data values for a given output pixel can be biased by a preset amount for each input image
- outliers can be masked and rejected

Mathematical Description:

None

6.9.2 Function Parameters

vir_fits ****fset** [float]

The input list of images to be combined.

int **nfits**

The number of input images

int combtype

A flag to determine whether the output should be a mean or a median of the input frames. 1 == median, 2 == mean

int scaletype

A flag to determine how the input will be scaled or biased before combining.

0: No scaling or biasing

1: Input files are biased additively to a common background median

2: Input files are scaled multiplicatively to a common background median

3: Input files are first scaled by exposure time and then biased to a common background.

int **xrej**

If set, then an extra rejection cycle will be performed. This is quite useful doing combinations in the region of bright objects.

float **thresh**

The rejection threshold in units of the background noise.

cpl_image ****outimage** [float]

The output combined image

unsigned char ****rejmask**

The output rejection mask. The value for each pixel tells how many input pixels were rejected at that position.

unsigned char ****rejplus**

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Listury Design	Date:	2006-12-12
System		Page:	67 of 145

The output positive residual rejection mask. The value for each pixel tells how many input pixels were rejected for having residuals that were positive. This is good for determining the number of cosmic ray hits there were on the input images.

cpl_propertylist ****drs**

An output propertylist for the provenance keywords to go in the DRS extension of the output file header.

int *status

Input/output status from function

6.9.3 Required Input FITS Header Information

The following is required to be in the extension header for each image in fset.

keyword	type	description
EXPTIME	float	The exposure time for each input image. This is used when doing
		multiplicative scaling

6.9.4 Output FITS Header Information

The following will appear in the extension header of **outimage**.

keyword	type	description
DRS PROVXXXX		A set of keywords that describes the provenance of the
		output file.

6.9.5 QC1 Outputs

None

6.9.6 Quality Assessment

6.9.7 Fatal Error Conditions

- Unable to map input data arrays
- Unable to create output data arrays

6.9.8 Non-Fatal Error Conditions

• Input frame set is empty

6.10 vircam_imcore

6.10.1 General

Name:

vircam_imcore

Purpose:

Generate a catalogue of objects on an image.

General Description:

This function is the main object extraction routine. It generates object catalogues for the purposes of astrometric and photometric calibration, generating catalogues of the form described in section 5.12. As a final step each object is given a stellar/non-stellar classification.

Mathematical Description:

This function implements the mathematical description in section 2.14

6.10.2 Function Parameters

vir_fits ***infile** [float]

The input frame from which to extract the objects

vir_fits *conf [int]

The input confidence map

int ipix

The minimum size of an object in pixels in order for that object not to be considered spurious.

float **thresh**

The detection threshold measured in units of the mean background noise int **icrowd**

If set, then the function will attempt to de-blend merged objects

float **rcore**

The core radius in pixels for the default profile fit.

int nbsize

The size in pixels of the grid squares used for background estimation.

int cattype

The output catalogue type. This can be:

- 1. The 32 column INT Wide Field Camera format
- 2. The 80 column WFCAM format
- 3. A very minimal format which is just fine if only positions are required.
- 4. An object mask

NB: option 1 corresponds to the catalogues described in section 5.12.

float filtfwhm

The FWHM of the smoothing kernel used in the detection algorithm

cpl_table ****outtab**

The output table of all the detected objects

cpl_propertylist **extra

A propertylist with QC information that one can append to a FITS header int *status

Input/output status from function

6.10.3 Required FITS Header Information

The following information is required from the extension header of **infile**.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010

keyword	type	Description
EXPTIME	int	The exposure time of the input data in seconds

6.10.4 Output FITS Header Information

The following will be written to the extension propertylist of the input image

keyword	type	Description
DRS SKYLEVEL	float	The mean sky level in the image
DRS SKYNOISE	float	The mean sky noise in the image
DRS THRESHOL	float	The threshold in ADUs for the image detection
DRS RCORE	float	The core radius in pixels as specified in the parameter list
DRS FILTFWHM	float	The FWHM of the smoothing kernel in the detection
		algorithm
DRS SEEING	float	The derived seeing in pixels
DRS CLASSIFD	int	If set, then this catalogue has been classified
DRS MINPIX	int	The minimum number of pixels an object should cover
DRS CROWDED	int	If set, then the deblending software has been run on this
		catalogue

6.11 vircam_imdither

6.11.1 General

Name:

vircam_imdither

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Library Dongi	Date:	2006-12-12
System		Page:	70 of 145

Purpose:

Dither all the images in a jitter sequence into a single output image

General Description:

This function takes all the images and their associated confidence maps from a jitter sequence and dithers them into a single output image and confidence map.

Mathematical Description:

None

6.11.2 Function Parameters

vir_fits **infiles [float]

The input images to dither

vir_fits **inconfs [int]

The associated input confidence maps

int **ninputs**

The number of input images in the jitter sequence

int **nconfs**

The number of input confidence maps. If this is the same as **ninputs** then it is assumed that each confidence map in the input list is associated with the image located in the same place of the input image list. If this is less than **ninputs** then the first confidence map in the list will be used for all of the input images.

cpl_propertylist *p

An output property list which can be used for the extension header for the output image. This will be the extension header for the first image in the list, but with appropriate modifications to the WCS.

cpl_image ****out**

The output dithered image.

cpl_image ****outc**

The output confidence map for the dithered image

int *status

Input/output status from function

6.11.3 Required FITS Header Information

The following information is required from the extension header of **infile**.

keyword	type	Description
EXPTIME	int	The exposure time of the input data in seconds
DRS XOFFDITHER	float	The jitter offset in <i>x</i>
DRS YOFFDITHER	float	The jitter offset in <i>y</i>

6.11.4 Output FITS Header Information

The following will be written to the extension propertylist of the input image

keyword	type	Description
DRS PROVXXXX	char	A set of keywords that describes the provenance of the
		output file.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010

6.12 vircam_interleave

6.12.1 General

Name:

vircam_interleave

Purpose:

Interleave the pixels from a microstepped sequence to form an output frame and confidence map.

General Description:

The fractional microstep and offsets defined by the WCS in the input file headers are used to define the size and scale of the output grid. The input data is then mapped directly onto the output grid using known offsets. The result is a frame where the input pixels have been interwoven to form a finer grid. The images can have the following done to them before combination:

- the input data values for a given output pixel can be scaled by a preset amount for each input image
- the input data values for a given output pixel can be biased by a preset amount for each input image

No pixel rejection is possible

Mathematical Description:

None

Quality Assessment:

N/A

6.12.2 Function Parameters

vir_fits ****infiles**

The list of input microstepped observation images

int **ninputs**

The number of input files in **infiles**.

vir_fits **inconfs

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	72 of 145

The list of input confidence maps. If the list is NULL or has a size of zero, then no output confidence map will be created. If the list has a size that is less than the size of the input file list (**infiles**), then only the first one will be used (i.e. each input image has the same confidence map). If the list has the same number of maps as the input images, then all the listed confidence maps will be used to form the output confidence map.

int **nconfs**

The number of confidence maps in **inconfs**.

int nsteps

The number of steps in the microstep pattern, e.g. for a 3x3 microstep pattern, this should be set to 3.

cpl_propertylist **p

A propertylist that will be used for the output image. This will be the header for the first image in the input image frameset (**infiles**), with the appropriate modifications to the WCS.

cpl_image **outimage

The output interleaved image

cpl_image **outconf

The output confidence map (if any)

int *status

Input/output status from function

6.12.3 Required Input FITS Header Information

The following information is required from the extension header of the first file in the **infiles** list.

keyword	type	description
CRPIX1	double	All of the standard FITS WCS keywords that are relevant for the
CRPIX2	double	projection model to be used with VIRCAM (nominally ZPN).
CTYPE1	char	See [RD 8] for more specific information.
CTYPE2	char	
CRVAL1	double	
CRVAL2	double	
CD1_1	double	
CD1_2	double	
CD2_1	double	
CD2_2	double	
PV2_1	double	
PV2_3	double	

The following information is required from the extension header from each of the files in the **infiles** list.

keyword	type	description
DRS XOFFMICRO	float	The X offset in pixels of the current image relative to the
		first image in the microstep sequence.
DRS YOFFMICRO	float	The Y offset in pixels of the current image relative to the

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010

6.13 vircam_lincor

6.13.1 General

Name:

vircam_lincor

Purpose:

Use linearity coefficients and timing information to put input data onto a linear scale.

General Description

The linearity coefficients for each data channel are combined with readout timing information in the manner described in section 2.2.1 to create a linearised data array for the input file.

Mathematical Description:

This function implements the mathematical description given in section 2.2.1. See that section for a full description.

6.13.2 Function Parameters

vir_fits *infile

The input image to be linearised

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	74 of 145

vir_tfits *lchantab

The channel table which is appropriate for this image.

int kconst

If set, then the value of k in section 2.2 is constant for all pixels in the image.

int *status

Input/output status from function

6.13.3 Required Input FITS Header Information

The following items are required from the extension header of infile.

keyword	type	description
EXPTIME	float	The exposure time for the image
ESO DET MINDIT	float	The minimum DIT time
ESO DET DITDELAY	float	A delay between the reset and the first read

6.13.4 Output FITS Header Information

The following items will appear in the extension header of **infile**:

keyword	type	description
DRS LINCOR	char	The name of the FITS file of the channel table used to
		linearise the data

6.13.5 QC1 Outputs

6.14 vircam_matchstds

6.14.1 General

Name:

vircam_matchstds

Purpose:

Match a list of standard stars (from vircam_getstds) to the (x,y) positions of objects on an image.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	75 of 145

General Description:

This routine matches the objects found on an image with a list of objects that have been extracted from a standard catalogue. The (x,y) coordinates in both lists are compared and Cartesian offsets are found which cause the maximum number of objects to match. Output will be to a matched standards table (5.13).

Mathematical Description:

N/A

6.14.2 Function Parameters

cpl_table *objtab

The input table with the programme objects. Must have columns called

X_coordinate and Y_coordinate (as one gets from *vircam_imcore*).

cpl_table *stdstab

The input table with the template objects. Must have columns called **xpredict** and **ypredict** (as one gets from *vircam_getstds*)

float srad

A search radius in pixels. This helps to define the number of points used in the grid search

cpl_table ****outtab**

The output table with both sets of Cartesian coordinates plus any extra information that appears in **stdstab**.

int *status

Input/output status from function

System		Page:	76 of 145

6.15 vircam_matchxy

6.15.1 General

Name:

vircam_matchxy

Purpose:

Work out relative jitter offsets by cross-correlating the locations of objects on a set of frames.

General Description:

Two catalogues of objects derived from two images (a programme image and a template image) are given. A search algorithm is used to try and maximise the number of objects that match between the two lists, by varying the Cartesian offsets. No axis flipping or rotation is allowed. The output is the x,y offsets. These can be applied to a whole group of files by the calling routine in order to define the relative offsets for a complete jitter sequence. The offsets are defined in the sense:

 $\Delta X = X_{\textit{template}} - X_{\textit{programme}}$

In order to minimise the effect of the astrometric distortion on the offset solution, it is generally advisable that the input coordinates of the programme table should be biased by offsets that have been calculated from the initial WCS in the input images.

Mathematical Description:

None

6.15.2 Function Parameters

cpl_table *progtab

The table of objects appearing on the 'programme' frame. Must have columns **X_coordinate** and **Y_coordinate**.

cpl_table *temptab

The table of objects appearing on the 'template' frame. Must have columns $X_coordinate$ and $Y_coordinate$.

float srad

The search radius in pixels. This is used to define the number of points for the grid search.

float *xoffset

The returned value of the *x* Cartesian offset

float ***yoffset**

The returned value of the *y* Cartesian offset

int *nm

The number of objects that matched between the two input lists

int *status

Input/output status from function

6.16 vircam_mkconf

6.16.1 General

Name:

vircam_mkconf

Purpose:

Make an initial confidence map from two flat field images

General Description:

A mean flat field image and a bad pixel mask are given. The good pixels are given a confidence value as described below and the bad ones are assigned a value of zero.

Mathematical Description:

'Good' pixels will be given a confidence of:

 $C_i = 100 F_i / \langle F \rangle$

where F_i is the pixel's value in the input flat field map, and $\langle F \rangle$ is the mean

value in the flat field map. A maximum confidence of 110 is allowed.

Quality Assessment:

N/A

6.16.2 Function Parameters

6.17 vircam_persist

6.17.1 General

Name:

vircam_persist

Purpose:

Remove effects of image persistence

General Description:

Images can persist on an IR detector after it has been read and reset. This persistence can be characterised by an exponential decay time. To correct this, a list of all the images that have been taken before the current image should be passed into this routine, along with their respective observational end times (in seconds from some zero point). This is the persistence mask defined in section 5.10. Using this information, an appropriate decay model and the ending time of the current exposure, a persistence map is built up. This map is then subtracted from the input image.

Mathematical Description:

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	79 of 145

This function implements the mathematical description in section 2.8.

6.17.2 Function Parameters

float decay

The decay constant in seconds as described in section 2.8.

float **fract**

The fraction of the ambient intensity that persists right after reset (i.e. no decay time).

6.17.3 Input Images and Required FITS Header Information

infile (float)

The input science image to be corrected.

keyword	type	description
EXPTIME	int	The exposure time of the input data
DATE-OBS	char	The UTC date of the start of the exposure

6.17.4 Input Tables

ptable

The persistence mask. See section 5.10.

6.17.5 Output Images

outfile (float)

The output science image; if this is the same as the value for **infile** or is blank, then the output will overwrite the input.

keyword type		description	
DRS PERMASK char		The name of the persistence	
		mask used	

6.17.6 Output Tables

None

6.17.7 Other Output

None.

6.17.9 Quality Assessment

Persistent images removed to within the mean sky noise.

6.17.10 Error Conditions

- The following conditions will cause fatal errors
 - Negative or zero exposure time.
 - Mismatched dimensionality of data arrays.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	80 of 145

• There are no non-fatal error conditions

6.18 vircam_photcal

6.18.1 General

Name:

vircam_photcal

Purpose:

Work out the photometric zero point for stars in an image

General Description:

The instrumental and standard magnitudes of objects on a frame are compared and a photometric zero point is calculated.

Mathematical Description:

This function implements the mathematical description in section 2.15

6.18.2 Function Parameters

vir_fits **images

The input list of images

cpl_table ****mstds**

The list of matched standards tables (section 5.13), one for each input image cpl_propertylist ****pl**

An array of propertylists representing the headers of the object catalogues that were derived from the input images.

int nimages

The number of images, matched standards catalogues and propertylists.

char *filt

The name of the filter for these observations.

cpl_table ***photcal**

The photometric calibration table (section 5.15)

int *status

The input/output function status

6.18.3 Required FITS Header Information

The following information is required in the extension header of the catalogues (see the parameter **pl**)

keyword	type	description	
EXPTIME	float	The exposure time in seconds	
APCOR3	float	The aperture correction for aperture 3 as calculated	
		by vircam_imcore	
APCOR5	float	The aperture correction for aperture 5 as calculated	
		by vircam_imcore	
ESO QC SATURATION	float	The saturation level in counts	
ESO DRS RCORE	float	The core radius used in the object detection	

The following information is required from the primary header of the images

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	81 of 145

keyword	type	description
ESO TEL AIRM START	float	The airmass at the start of the observation.

6.18.4 Output FITS Header Information

This routine calculates a zeropoint for two different apertures. It calculates these for each individual image and calculates a collective zeropoint for all the images in the list. In the table below the suffix "im" refers to results on an image by image basis and 'all' refers to the collective solution.

keyword	type	description
DRS ZPIM3	float	The calculated photometric zero point for the image in
		aperture 3
DRS ZPSIGIM3	float	The RMS of the photometric zero point for the image
		in aperture 3
DRS ZPIM5	float	The calculated photometric zero point for the image in
		aperture 5
DRS ZPSIGIM5	float	The RMS of the photometric zero point for the image
		in aperture 5
DRS LIMIT_MAG3	float	6 6 6 6
		aperture 3
DRS LIMIT_MAG5	float	6 6 6 6
		aperture 5
DRS MAGNZPTIM	int	The number of stars used in the zero point calculation
		in this image
DRS ZPALL3	float	The calculated photometric zero point for all images in aperture 3
DRS ZPSIGALL3	float	1
		in aperture 3
DRS ZPALL5	float	The calculated photometric zero point for all images in
		aperture 5
DRS ZPSIGALL5	float	The RMS of the photometric zero point for all images
		in aperture 5
DRS MAGNZPTALL	int	The number of stars used in the zero point calculation
		in all images

6.18.5 QC1 Outputs

6.18.6 Quality Assessment

The RMS of the zeropoint is with the expected limits of the 2MASS catalogue, notwithstanding the quality of the observing conditions.

6.18.7 Fatal Error Conditions

- Photometric calibration table is incomplete
- No input images
- No rows in matched standards catalogue
- Missing header information in standards catalogue or image

6.18.8 Non-Fatal Error conditions

None

6.19 vircam_platesol

6.19.1 General

Name:

vircam_platesol

Purpose:

Work out a plate solution for an image given the RA, Dec, *x*, *y* values for objects on that image.

General Description:

Cartesian and equatorial coordinates are fitted to standard plate solution models of either 4 or 6 constants (4-constant model being more robust but at the cost of assuming zero shear and no scale difference. The default therefore is 6). If so desired, the difference in the predicted x, y coordinates and the true x, y coordinates can be used to adjust the tangent point first to block correct for telescope pointing error. The median difference of the equatorial coordinates between that implied from the two sets of Cartesian coordinates is used to update the tangent point. A full least-squares solution is performed and the results are written back to the given FITS WCS header structure.

Mathematical Description:

For a 6 constant model, fits are done with the input standards for the equations:

$$\xi = ax + by + c \tag{6-1}$$

$$\eta = dx + ey + f \tag{6-2}$$

to find values of a, b, c, e, d and f. For a 4-constant model the same equations are used, but with the constraint that a = e and b = d. See section 2.10 for information on how the expected projection geometry will be incorporated.

6.19.2 Function Parameters

cpl_propertylist *plist

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	83 of 145

The propertylist which represents the FITS header for an input image. It must have a rough FITS WCS already if the tangent point is going to be repositioned.

cpl_table *matchedstds

A matched standards table containing at least the following columns: **X_coordinate**, **Y_coordinate**, **xpredict**, **ypredict**, **ra**, **dec**.

int **nconst**

The number of plate constants to be used. This can be either 6 (default) or 4. int **shiftan**

If set, then the difference between the predicted and the true cartesian coordinates of the objects in the matched standards catalogue will be used to redefine the equatorial coordinates of the reference point of the WCS.

int *status

The input/output function status.

6.19.3 Required FITS Header Information

keyword	type	description
CRPIX1	double	All of the standard FITS WCS keywords that are relevant for
CRPIX2	double	the projection model to be used with VIRCAM (nominally
CTYPE1	char	ZPN). See [RD 8] for more specific information. NB: These
CTYPE2	char	will all be modified by this function on output.
CRVAL1	double	
CRVAL2	double	
CD1_1	double	
CD1_2	double	
CD2_1	double	
CD2_2	double	
PV2_i,	double	
i=1~5		
NAXIS1	int	The X size of the data array from which the catalogue was
		generated
NAXIS2	int	The Y size of the data array from which the catalogue was
		generated

6.19.4 Output FITS Header Information

As above, but modified by the fit done in this routine, also:

keyword	type	description
DRS STDCRMS	float	The RMS of the WCS fit.
DRS NUMBRMS	int	The number of stars used in the WCS fit
DRS WCSRAOFF	float	The equatorial coordinates of the central pixel of the image is calculated both before and after the plate solution is found. This is the difference in the RA (in arcseconds)

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	84 of 145

DRS WCSDECOFF	float	The equatorial coordinates of the central pixel of the
		image is calculated both before and after the plate
		solution is found. This is the difference in the DEC (in
		arcseconds)

6.19.5 QC1 Outputs

WCS_DCRVAL1 WCS_DCRVAL2 WCS_DTHETA WCS_SCALE WCS_SHEAR (6-constant model) WCS_RMS

6.19.6 Quality Assessment

DRS STDCRMS is within the expected internal consistency of the input astrometric data convolved with a centring error.

6.19.7 Fatal Error Conditions

- Unsupported value of **nconst**.
- Too few standards for the fit.
- Required columns don't exist in input matched standards table.

6.19.8 Non-Fatal Error conditions

None

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	85 of 145

7 Data Reduction CPL Plugins

Each recipe has a direct correspondence to a CPL plugin; but the correspondence between raw data-types and recipes is not one-to-one because, in some cases, science data are used to produce calibration frames. Each plugin is documented below. Where a calibration product is created by the recipe, the value in parenthesis after the file specifies the value of the PRO CATG keyword in the output file header. The parenthesis after the input data specifications indicate whether the data are required or optional and the DO CATG keyword that must appear in the sof file.

The plugins may receive error messages from the functions that they call. If these are considered by the function to be fatal, then the plugin will exit gracefully. If the errors are considered to be just a warning the plugin may choose to proceed with caution, to get the information it needs from another source or fail gracefully. As in the previous section we do not include conditions such as segmentation violations and arithmetic exceptions in the list of fatal errors. Only error conditions that occur within the plugin, and outside of the VIRCAM functions documented in section 6, will be documented here. In addition, all error conditions which would lead to the writing of a dummy product will be documented here. All recipes will fail if they are unable to identify RAW and CALIB frames or if they cannot make sense of the DO CATG values specified in the sof file.

All of the parameters that can be changed on the command line are listed for each recipe. It is worth noting that **esorex** allows the user to change parameters in a semipermanent way using environment variables. Full details on the names of these environment variables can be found by using the **-man-page** switch with **esorex**. Finally all recipes have a parameter that is in addition to the ones documented below. This is **ext** and it defines the FITS extension number for the input files that are to be processed by the recipe. This allows the recipe to either process a single extension or all extensions (**ext** = 0).

7.1 vircam_reset_combine

Name:

vircam_reset_combine

Purpose:

Combine a sequence of reset frames to form a mean frame. Compare to a library reset frame to provide information on the stability of the pedestal and reset structure

Type:

Detector calibration

Input Data:

- List of reset frames (required, RESET_IMAGE)
- Library mean reset frame (optional, MASTER_RESET)
- Channel table (optional, CHANNEL_TABLE)
- Library bad pixel map (optional, MASTER_BPM) or library confidence map (optional, MASTER_CONF)

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	j _ 08-g	Date:	2006-12-12
System		Page:	86 of 145

Parameters:

int combtype

Determines the type of combination that is done to form the output map. Can take the following values

- 1. The output pixels are medians of the input pixels
- 2. The output pixels are means of the input pixels

int scaletype

Determines how the input data are scaled or offset before they are combined. Can take the following values:

- 0. No scaling or biasing
- 1. All input frames are biased additively to bring their backgrounds to a common median level.
- 2. All input frames are biased multiplicatively to bring their backgrounds to a common median level.
- 3. All input frames are scaled to a uniform exposure time and then additively corrected to bring their backgrounds to a common median level.

int **xrej**

If set, then an extra rejection cycle will be run.

int **thresh**

The rejection threshold in numbers of background sigmas.

int ncells

If a difference image statistics table is being done, then this is the number of cells in which to divide each readout channel. The value must be a power of 2, up to 64

Algorithm:

- Combine the sequence of reset frames into a single mean with rejection.
- Calculate RMS of mean reset frame.
- If a library master reset frame is given, then subtract it from the mean frame created here to form a difference image. Calculate a mean and RMS of the difference image.
- If a channel map is included, then this is used to split each data channel of the difference image into cells and do a robust median and RMS estimate in each. The results of this analysis are written to a difference image statistics table.
- If a master bad pixel mask or a master confidence map is included these are used to mask out bad pixels in the above statistical analyses.

Outputs:

- New master reset frame (MASTER_RESET)
- Difference image (DIFFIMG_RESET)
- Reset difference image statistics table (DIFFIMG_STATS_RESET)

QC1 Parameters:

RESETMED RESETRMS RESETDIFF_MED RESETDIFF_RMS

VIRCAM Functions Used:

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	87 of 145

vircam_imcombine

Fatal Error Conditions:

- Null input frameset
- Input frameset headers incorrect meaning that RAW and CALIB frames cannot be distinguished
- No reset frames in the input frameset
- Inability to save output products

Non-fatal Error Conditions:

- Missing calibDB reset frame (No comparison with master frame done and no output difference image)
- Missing or invalid channel table (No difference image statistics table made)
- Missing bad pixel map or missing confidence map (No bad pixel rejection during statistical analysis)

Conditions Leading To Dummy Products:

- Reset frame image extensions won't load
- The detector for the current image extension has been disabled
- Failure in combination routine
- Master reset frame image extension won't load or is a dummy
- Channel table FITS extension won't load, is invalid or is a dummy

7.2 vircam_dark_combine

Name:

vircam_dark_combine

Purpose:

Combine a series of dark frames taken with a particular integration and exposure time combination. Compare with a similarly observed master dark frame. Calculate variation in the reset anomaly structure and scale.

Type:

Detector calibration

Input Data:

- List of dark frames (required, DARK_IMAGE)
- Library mean dark frame (optional, MASTER_DARK)
- Library bad pixel mask (optional, MASTER_BPM) or library confidence map (optional, MASTER_CONF)
- Channel table (optional, CHANNEL_TABLE)

Parameters:

int combtype

Determines the type of combination that is done to form the output map. Can take the following values

- 1. The output pixels are medians of the input pixels
- 2. The output pixels are means of the input pixels

int scaletype

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	88 of 145

Determines how the input data are scaled or offset before they are combined. Can take the following values:

- 0. No scaling or biasing
- 1. All input frames are biased additively to bring their backgrounds to a common median level.
- 2. All input frames are biased multiplicatively to bring their backgrounds to a common median level.
- 3. All input frames are scaled to a uniform exposure time and then additively corrected to bring their backgrounds to a common median level.

int **xrej**

If set, then an extra rejection cycle will be run.

int **thresh**

The rejection threshold in numbers of background sigmas.

int ncells

If a difference image statistics table is being done, then this is the number of cells in which to divide each readout channel. The value must be a power of 2, up to 64

Algorithm:

- Combine the sequence of dark frames with rejection.
- In conjunction with bad pixel map or confidence map, assess the number of rejected pixels with positive residuals to give an indication of the rate of cosmic ray hits and their properties.
- Work out a robust median in a region that is unaffected by reset anomaly.
- If a library master dark frame is given, then subtract it from the mean frame created here to form a difference image. Calculate a mean and RMS of the difference image.
- If a channel map is included, then this is used to split each data channel of the difference image into cells and do a robust median and RMS estimate in each. The results of this analysis are written to a difference image statistics table.
- If a master bad pixel mask or a master confidence map is included these are used to mask out bad pixels in the above statistical analyses

Outputs:

- New mean dark frame (MASTER_DARK)
- Dark frame difference image (DIFFIMG_DARK)
- Dark difference image statistics table (DIFFIMG_STATS_DARK)

QC1 Parameters:

DARKMED DARKRMS DARKDIFF_MED DARKDIFF_RMS PARTICLE_RATE STRIPERMS

VIRCAM Functions Used:

vircam_imcombine, vircam_destripe

Fatal Error Conditions:

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	89 of 145

- Null input frameset
- Input frameset headers incorrect meaning that RAW and CALIB frames cannot be distinguished
- No dark frames in the input frameset
- Inability to save output products

Non-fatal Error Conditions:

- Missing calibDB dark frame (No comparison with master frame done and no output difference image)
- Missing or invalid channel table (No difference image statistics table made)
- Missing bad pixel map or missing confidence map (No bad pixel rejection during statistical analysis)

Conditions Leading To Dummy Products:

- Dark frame image extensions won't load
- The detector for the current image extension has been disabled
- Failure in combination routine
- Master dark frame image extension won't load or is a dummy
- Channel table FITS extension won't load, is invalid or is a dummy

7.3 vircam_dark_current

Name:

vircam_darkcurrent

Purpose:

Calculate the dark current of a detector using a series of dark exposures with varying exposure times.

Type:

Detector Calibration

Input Data:

- A series of dark exposures at a variety of different exposure times (required, DARK_IMAGE)
- Library bad pixel mask (optional, MASTER_BPM) or library confidence map (optional, MASTER_CONF)

Parameters:

float thresh

The threshold in units of background sigma above or below the local mean value. This defines whether a data point in the fit is bad or not.

Algorithm:

- Perform robust iterative linear fit across all exposures at each pixel position
- At each pixel position, the slope of the fit represents the dark current expressed in units of ADUs per second.
- Where the bad pixel mask is set the output value is set to zero.

Outputs:

• Dark current map (MASTER_DARK_CURRENT)

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	90 of 145

QC1 Parameters:

DARKCURRENT

VIRCAM Functions Used:

None

Fatal Error Conditions:

- Null input frameset
- Input frameset headers incorrect meaning that RAW and CALIB frames cannot be distinguished
- Not enough dark frames in the input frameset
- Missing exposure times in input headers
- Inability to save output products

Non-fatal Error Conditions:

• Missing bad pixel map or missing confidence map (No bad pixel rejection during statistical analysis)

Conditions Leading To Dummy Products:

- Dark frame image extensions won't load
- The detector for the current image extension has been disabled

7.4 vircam_dome_flat_combine

Name:

vircam_dome_flat_combine

Purpose:

Combine a series of dome flat images to create a mean dome flat. Compare with a similarly observed master dome flat frame.

Type:

Detector calibration

Input Data:

- List of dome flat exposures all taken with the same exposure parameters (required, DOME_FLAT)
- Master dark frame of the same exposure parameters as above (required, MASTER_DARK)
- Master mean dome flat (optional, MASTER_DOME_FLAT)
- Channel map (optional, CHANNEL_TABLE)
- Master bad pixel mask (optional, MASTER_BPM) or master confidence map (optional, MASTER_CONF)

Parameters:

float **lthr**

Any input flat with a mean value of less than this will be excluded as being underexposed.

float hthr

Any input flat with a mean value of more than this will be excluded as being overexposed.

int combtype

Determines the type of combination that is done to form the output map. Can take the following values

1. The output pixels are medians of the input pixels

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	91 of 145

2. The output pixels are means of the input pixels

int scaletype

Determines how the input data are scaled or offset before they are combined. Can take the following values:

- 0. No scaling or biasing
- 1. All input frames are biased additively to bring their backgrounds to a common median level.
- 2. All input frames are biased multiplicatively to bring their backgrounds to a common median level.
- 3. All input frames are scaled to a uniform exposure time and then additively corrected to bring their backgrounds to a common median level.

int **xrej**

If set, then an extra rejection cycle will be run.

int **thresh**

The rejection threshold in numbers of background sigmas.

int ncells

If a ratio image statistics table is being done, then this is the number of cells in which to divide each readout channel. The value must be a power of 2, up to 64

Algorithm:

- Remove any images that are saturated or underexposed.
- Process remaining images to linearise and remove dark current.
- Combine the dome flat exposures with rejection.
- If a library master dome flat frame is given, then divide the mean frame created here into the master to form a ratio image. Calculate a mean and RMS of the ratio image.
- If a channel map is included, then this us used to split each data channel of the ratio image into cells and do a robust median and RMS estimate in each. The results of this analysis are written to a ratio image statistics table.
- If a master bad pixel mask or a master confidence map is included these are used to mask out bad pixels in the above statistical analyses

Outputs:

- New master dome flat (MASTER_DOME_FLAT)
- Ratio image (RATIOIMG_DOME_FLAT)
- Ratio image statistics table (RATIOIMG_DOME_FLAT_STATS)

QC1 Parameters:

FLATRMS

FLATRATIO_MED

FLATRATIO_RMS

VIRCAM Functions Used:

vircam_imcombine, vircam_darkcor, vircam_lincor

Fatal Error Conditions:

- Null input frameset
- Input frameset headers incorrect meaning that RAW and CALIB frames cannot be distinguished

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	92 of 145

- No dome flat frames in the input frameset
- No master dark frame in input frameset
- Inability to save output products

Non-fatal Error Conditions:

- Missing calibDB dome frame (No comparison with master frame done and no output ratio image)
- Missing or invalid channel table (No ratio image statistics table made)
- Missing bad pixel map or missing confidence map (No bad pixel rejection during statistical analysis and no linearisation done)

Conditions Leading To Dummy Products:

- Dome frame image extensions won't load
- The detector for the current image extension has been disabled
- All the dark corrected images are either below the under-exposure threshold or above the over-exposure threshold.
- Master dark frame image extension won't load or is a dummy
- Failure in combination routine
- Channel table FITS extension won't load, is invalid or is a dummy

7.5 vircam_detector_noise

Name:

vircam_detector_noise

Purpose:

Measure the detector readout noise and gain

Type:

Detector calibration

Input Data

- Two dome flat frames taken with the same exposure parameters (required, DOME_FLAT)
- Two dark frames taken with the same exposure parameters as the dome flats (required, DARK_IMAGE)
- A master bad pixel mask (optional, MASTER_BPM) or master confidence map (MASTER_CONF)

Parameters:

float **thresh**

The threshold in units of background sigma above or below the local mean value. This is used during the statistical analyses of the input images and difference images.

Algorithm:

- Form difference images of the two dome flats and the two dark frames
- Do statistics as outlined in section 2.4 to give an estimate of read noise and gain

Outputs:

• Read noise and gain estimates for each extension. These are written to a paf file.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	93 of 145

• Read noise and gain estimates for each extension written to a detector noise table (READGAIN_TABLE)

QC1 Parameters:

READNOISE

GAIN

VIRCAM Functions Used:

None

Fatal Error Conditions:

- Null input frameset
- Input frameset headers incorrect meaning that RAW and CALIB frames cannot be distinguished
- Insufficient dark or flat exposures
- Inability to save output products

Non-fatal Error Conditions:

• Missing bad pixel map or missing confidence map (No bad pixel rejection during statistical analysis and no linearisation done) No stats are calculated.

Conditions Leading To Dummy Products:

- The image extensions won't load
- Unphysical statistical result
- The detector for the current image extension is flagged dead.

7.6 vircam_linearity_analyse

Name:

vircam_linearity_analyse

Purpose:

Create detector channel linearity curves and bad-pixel maps

Type:

Detector calibration

Input Data:

- A series of dome flat exposures taken under constant illumination with varying integration times (required, DOME_FLAT).
- Channel map (required, CHANNEL_TABLE)
- A list of raw dark frames containing a series of dark exposures with the same exposure parameters for each of the input dome flat exposures (required, DARK_IMAGE)

Parameters:

int **nord**

The order of the polynomial to be fit to the linearity curve of each channel

float lthr

The lower threshold in the ratio maps to define a pixel as bad. Units are in background sigma of the ratio map.

float **hthr**

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Library Dosign	Date:	2006-12-12
System		Page:	94 of 145

The upper threshold in the ratio maps to define a pixel as bad. Units are in background sigma of the ratio map

float overexp

The maximum number of ADUs a dome flat image may have on average before it is considered to be over-exposed.

Algorithm:

- Combine all sets of raw dark images into mean dark images
- Process each flat exposure by removing the reset anomaly with the appropriate dark frame
- Combine the dome series with rejection into a normalised mean flat field
- Divide the series by the mean frame
- Find pixels in the ratio maps whose values are over or under the input threshold value and flag them as bad
- Compute the number of bad pixels in this new bad pixel mask.
- Combine timing information from channel map and known read and reset times to derive the *k* factors needed as indicated in section 2.2.2.
- Solve for coefficients and store them in a new channel table.

Outputs:

- Output channel table with new linearity information (CHANTAB)
- Output bad pixel mask (MASTER_BPM)

QC1 Parameters:

LINEARITY LINFITQUAL BAD PIXEL STAT

VIRCAM Functions Used:

vircam darkcor, vircam genlincur

Fatal Error Conditions:

- Null input frameset
- Input frameset headers incorrect meaning that RAW and CALIB frames cannot be distinguished
- No dark or dome flat frames in input frameset
- No channel table in input frameset
- Inability to save output products

Non-fatal Error Conditions:

• Not enough dome flats in the series for the requested order of fit. Order is adjusted downwards.

Conditions Leading To Dummy Products:

- The dark/dome image extensions won't load
- Channel table fits extension won't load, won't verify or is flagged as a dummy.
- The detector for the current image extension is flagged dead.
- vircam_genlincur failed

7.7 vircam_twilight_flat_combine

Name:

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Liorary Doorgin	Date:	2006-12-12
System		Page:	95 of 145

vircam_twilight_flat_combine

Purpose:

Combine a series of twilight flat images to create a mean twilight flat and initial confidence map. Compare with a similarly observed master twilight flat frame.

Type:

Detector calibration

Input Data:

- List of twilight flat exposures all taken with the same exposure parameters (required, TWILIGHT_FLAT)
- Master dark frame of the same exposure parameters as above (required, MASTER_DARK)
- Master mean twilight flat (optional, MASTER_TWILIGHT_FLAT)
- Channel map (optional, CHANNEL_TABLE)
- Master bad pixel mask (optional, MASTER_BPM) or master confidence map (optional, MASTER_CONF)

Parameters:

float **lthr**

Any input flat with a mean value of less than this will be excluded as being underexposed.

float ${\boldsymbol{h}}{\boldsymbol{t}}{\boldsymbol{h}}{\boldsymbol{r}}$

Any input flat with a mean value of more than this will be excluded as being overexposed.

int combtype

Determines the type of combination that is done to form the output map. Can take the following values

- 1. The output pixels are medians of the input pixels
- 2. The output pixels are means of the input pixels

int scaletype

Determines how the input data are scaled or offset before they are combined. Can take the following values:

- 0. No scaling or biasing
- 1. All input frames are biased additively to bring their backgrounds to a common median level.
- 2. All input frames are biased multiplicatively to bring their backgrounds to a common median level.
- 3. All input frames are scaled to a uniform exposure time and then additively corrected to bring their backgrounds to a common median level.

int **xrej**

If set, then an extra rejection cycle will be run.

int thresh

The rejection threshold in numbers of background sigmas.

int ncells

If a ratio image statistics table is being done, then this is the number of cells in which to divide each readout channel. The value must be a power of 2, up to 64

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	96 of 145

Algorithm:

- Remove any images that are saturated or underexposed.
- Process remaining images to linearise and remove dark current.
- Combine the twilight flat exposures with rejection. Normalise by its median.
- If a library master twilight flat frame is given, then divide the mean frame created here into the master to form a ratio image. Calculate a mean and RMS of the ratio image.
- If a channel map is included, then this us used to split each data channel of the ratio image into cells and do a robust median and RMS estimate in each. The results of this analysis are written to a ratio image statistics table.
- If a master bad pixel mask or a master confidence map is included these are used to mask out bad pixels in the above statistical analyses
- Use the mean flat and bad pixel map to create an initial confidence map.

Outputs:

- New master twilight flat (MASTER_TWILIGHT _FLAT)
- Ratio image (RATIOIMG_TWILIGHT_FLAT)
- Ratio image statistics table (RATIOIMG_TWILIGHT_FLAT_STATS)
- New master confidence map (MASTER_CONF)

QC1 Parameters:

FLATRMS FLATRATIO_MED FLATRATIO_RMS GAIN CORRECTION

VIRCAM Functions Used:

vircam_imcombine, vircam_mkconf, vircam_darkcor, vircam_lincor

Fatal Error Conditions:

- Null input frameset
- Input frameset headers incorrect meaning that RAW and CALIB frames cannot be distinguished
- No twilight flat frames in input frameset
- No master dark frame in input frameset
- Inability to save output products

Non-fatal Error Conditions:

- No master twilight flat. No ratio image formed
- No master bad pixel map or confidence map. All pixels considered to be good.
- No channel table in input frameset. No ratio image stats table or linearisation will be done.

Conditions Leading To Dummy Products:

- The twilight frame image extensions won't load
- The detector for the current image extension is flagged dead.
- All the dark corrected images are either above the over exposure threshold or just below the under exposure threshold.
- Master dark extension won't load or is flagged as a dummy

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	97 of 145

- vircam_imcombine failed
- Master twilight flat image failed to load or flagged as a dummy
- Channel table fits extension failed to load or flagged as a dummy

7.8 vircam_mesostep_analyse

Name:

vircam_mesostep_analyse

Purpose:

Create a map of illumination corrections using a mesostep sequence of a standard stars

Type:

Detector calibration

Input Data:

- A series of exposures of a sparse secondary standard field that has been offset in a regular raster
- Library master dark frame for the given exposure and integration time
- Library master flat field for the given passband
- Library confidence map for the given passband *or* a library bad pixel mask
- Library fringe frame
- Linearity channel table
- Photometric calibration table
- Persistence mask
- Crosstalk table
- Photometric standard data (through VIRCAM interface to 2MASS)

Parameters:

int **ipix**

The minimum size of an object in pixels in order for that object not to be considered spurious.

float thr

The detection threshold measured in units of the mean background noise

int **icrowd**

If set, then the function will attempt to de-blend merged objects

float **rcore**

The core radius in pixels for the default profile fit.

int **nb**

The size in pixels of the grid squares used for background estimation char ***path2mass**

The full path to the 2MASS catalogue FITS files

int destripe

If this is set, then the input images will be de-striped. Not recommended for images that are likely to contain very large extended objects.

int skycor

If this is set, then the input images are stacked with rejection to form a mean background map. This is normalised to zero median and

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	98 of 145

subtracted off the input images. This is not recommended for images that are likely to contain extended sources.

int nord_

The order of the polynomial surface to be fit

Algorithm:

- Process the observations by linearising, dark correction and flat fielding
- Compute the zero-point of standard stars on of each of the exposures.
- Divide the area of the detector into cells and bin each of the zeropoint calculations into these cells.
- Work out a median zero point for each cell
- Fit the zeropoint solutions to a 2d polynomial.
- Evaluate the polynomial at the central grid points of each cell.
- Write the illumination correction table.

Outputs:

• Illumination correction table (see 5.7) (ILLCOR_TAB)

QC1 Parameters:

ILLUMCOR_RMS

VIRCAM Functions Used:

vircam_darkcor, vircam_lincor, vircam_flatcor, vircam_defringe, vircam_persist, vircam_crosstalk, vircam_imcore, vircam_getstds, vircam_matchstds

Fatal Error Conditions:

- Null input frameset
- Input frameset headers incorrect meaning that RAW and CALIB frames cannot be distinguished
- No science frames in input frameset
- Missing master calibration frames or unreadable extensions in input frameset
- Inability to save output products

Non-fatal Error Conditions:

None

Conditions Leading To Dummy Products:

- Missing calibration images, calibration images that won't load or are flagged as dummy.
- A detector has been signalled dead.
- Processing routines fail.

7.9 vircam_persistence_analyse

Name:

vircam_persistence_analyse

Purpose:

Analyse an image of bright stars and subsequent dark exposures to compute the persistence decay rate

Type:

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	99 of 145

Detector calibration

Input Data:

- An observation of bright stars taken close to saturation
- A master dark frame for the given integration time
- A master flat field for the given passband
- A master confidence map for the given passband
- Linearity channel table
- A series of dark exposures taken at regular time intervals afterwards

Parameters:

float **thresh**

Detection threshold for object extraction

Algorithm:

- Process the observation by linearising, dark correction and flat fielding
- Compute the flux and position of bright stars on an image.
- Look on subsequent dark exposures at the same location and compute the flux.
- Fit the flux vs. Δt curve to an exponential to work out the characteristic decay constant, τ_0 and the flux a zero time.

Outputs:

- Persistence decay time constant
- Persistence fraction at zero time

QC1 Parameters:

PERSIST_DECAY PERSIST_ZERO

PERSISI_ZERO

VIRCAM Functions Used:

vircam_darkcor, vircam_lincor, vircam_flatcor, vircam_defringe, vircam_imcore

Fatal Error Conditions:

- Missing master calibration frames
- Missing master calibration tables
- No dark frames available after star observation.

Non-fatal Error Conditions:

None

7.10 vircam_crosstalk_analyse

Name:

vircam_crosstalk_analyse

Purpose:

Analyse a series of images to work out the crosstalk matrix for all detector sections

Type:

Detector calibration

Input Data:

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	100 of 145

- A series of exposures of a bright star. The star should be centred in each of the instrument's data channels.
- Master flat and confidence map for the given passband
- Master dark frame for the given exposure time
- Channel table

Parameters:

float thresh

Detection threshold for object extraction

Algorithm:

- Locate objects on each exposure.
- Use channel table to predict location of crosstalk images of the bright star and locate the crosstalk image in the object catalogue.
- Create crosstalk matrix from the ratio of the fluxes for a given channel combination.

Outputs:

• Crosstalk matrix as described in 5.6 (XTALK)

QC1 Parameters:

CROSS_TALK

VIRCAM Functions Used:

vircam_imcore

Fatal Error Conditions:

- Missing channel table or confidence map
- **Non-fatal Error Conditions:**

None

7.11 vircam_jitter_microstep_process

Name:

vircam_jitter_microstep_process

Purpose:

Process a sequence of target data that may have been both jittered and microstepped.

Type:

Science

Input Data:

- A jittered and/or microstepped sequence of exposures of a target region.
- Library mean dark frame for the given exposure and integration time.
- Library mean flat field frame for the given passband
- Library confidence map for the given passband *or* a library bad pixel mask

• Library fringe frame

- Linearity channel table
- Readnoise/gain file
- Photometric calibration table
- Crosstalk matrix
- Persistence mask

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	101 of 145

- Astrometric standard data (through VIRCAM interface to 2MASS)
- Photometric standard data (through VIRCAM interface to 2MASS)

Parameters:

int **ipix**

The minimum size of an object in pixels in order for that object not to be considered spurious.

float thr

The detection threshold measured in units of the mean background noise

int icrowd

If set, then the function will attempt to de-blend merged objects float **rcore**

The core radius in pixels for the default profile fit.

int **nb**

The size in pixels of the grid squares used for background estimation char **path2mass**

The full path to the 2MASS catalogue FITS files

int **destripe**

If this is set, then the input images will be de-striped. Not recommended for images that are likely to contain very large extended objects.

int skycor

If this is set, then the input images are stacked with rejection to form a mean background map. This is normalised to zero median and subtracted off the input images. This is not recommended for images that are likely to contain extended sources.

int savecat

If set, then the catalogue generated during the astrometric and photometric calibration will be saved.

Algorithm:

Remove crosstalk images

- Process the images by linearising and removing dark current and flat fielding
- De-fringe
- Remove persistent images
- Correct for striping and sky background
- Work out microstep offsets using header information
- Combine the images into super-frames by interleaving using the microstep offsets
- Work out jitter offsets by cross-correlating stellar object positions on super-frame images
- Combine the super-frame images with offsets into a single stacked image
- Generate a catalogue of objects on the stacked image and do a morphological classification
- Fit a WCS using astrometric standards that appear in the stacked image catalogue. Update the FITS headers of the stacked image as well as those of the super-frames and the single exposure images.

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	102 of 145

- Calculate photometric zero point using instrumental magnitudes, magnitudes of photometric standards, and illumination corrections.
- Apply illumination correction to catalogue

Outputs:

- Single exposure images that corrected for linearity, dark current, flat field, stripes, sky, image persistence and crosstalk. A full WCS will appear in the header (SIMPLE_IMAGE)
- Interleaved super-frame images from the above if microstepping has been done as part of the observing sequence. (INTERLEAVED_IMAGE)
- Stacked jitter images from the super-frames. Full WCS and photometric zero point will appear in the FITS header. (JITTERED_IMAGE)
- Associated confidence maps for each of the above output images. (CONFIDENCE_MAP)
- Object catalogue in the form of a FITS table if the **savecat** parameter has been set (OBJECT_CATALOGUE)

QC1 Parameters:

FRINGE RATIO **SATURATION** MEAN SKY SKY NOISE NOISE OBJ IMAGE SIZE APERTURE CORR ELLIPTICITY MAGZPT MAGZERR MAGNZPT LIMITING MAG WCS DCRVAL1 WCS DCRVAL2 WCS DTHETA WCS SCALE WCS SHEAR WCS RMS

VIRCAM Functions Used:

vircam_darkcor, vircam_lincor, vircam_flatcor, vircam_defringe, vircam_persist, vircam_matchxy, vircam_crosstalk, vircam_imcore, vircam_getstds, vircam_platesol, vircam_matchstds, vircam_imdither, vircam_photcal

Fatal Error Conditions:

- Null input frameset
- Input frameset headers incorrect meaning that RAW and CALIB frames cannot be distinguished
- No science frames in input frameset
- Missing master calibration frames or unreadable extensions in input frameset

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	103 of 145

• Inability to save output products

Non-fatal Error Conditions:

None

Conditions Leading To Dummy Products:

- Missing calibration images, calibration images that won't load or are flagged as dummy.
- A detector has been signalled dead.
- Processing routines fail.

7.12 vircam_standard_process

Name:

vircam_standard_process

Purpose:

Process a sequence of photometric standard data that may have been both jittered and microstepped.

Type:

Science

Input Data:

- A jittered and/or microstepped sequence of exposures of a target region.
- Library mean dark frame for the given exposure and integration time.
- Library mean flat field frame for the given passband
- Library confidence map for the given passband or a library bad pixel mask

• Library fringe frame

- Linearity channel table
- Readnoise/gain file
- Photometric calibration table
- Crosstalk matrix
- Persistence mask
- Astrometric standard data (through VIRCAM interface to 2MASS)
- Photometric standard data (through VIRCAM interface to 2MASS and a second source if requested)

Parameters:

int **ipix**

The minimum size of an object in pixels in order for that object not to be considered spurious.

float thr

The detection threshold measured in units of the mean background noise

int icrowd

If set, then the function will attempt to de-blend merged objects

float **rcore**

The core radius in pixels for the default profile fit.

int **nb**

The size in pixels of the grid squares used for background estimation char ***path2mass**

The full path to the 2MASS catalogue FITS files

char *catpath

The full path to a second photometric catalogue

char *catname

The name of the second photometric catalogue

int **destripe**

If this is set, then the input images will be de-striped. Not recommended for images that are likely to contain very large extended objects.

int skycor

If this is set, then the input images are stacked with rejection to form a mean background map. This is normalised to zero median and subtracted off the input images. This is not recommended for images that are likely to contain extended sources.

int savecat

If set, then the catalogue generated during the astrometric and photometric calibration will be saved.

Algorithm:

- Remove crosstalk images
- Process the images by linearising and removing dark current and flat fielding
- De-fringe

• Remove persistent images

- Correct for striping and sky background
- Work out microstep offsets using header information
- Combine the images into super-frames by interleaving using the microstep offsets
- Work out jitter offsets by cross-correlating stellar object positions on super-frame images
- Combine the super-frame images with offsets into a single stacked image
- Generate a catalogue of objects on the stacked image and do a morphological classification
- Fit a WCS using astrometric standards that appear in the stacked image catalogue. Update the FITS headers of the stacked image as well as those of the super-frames and the single exposure images.
- Calculate photometric zero point using instrumental magnitudes, magnitudes of photometric standards, and illumination corrections.
- If a second photometric catalogue is specified, the redo the photometric zero point.
- Apply illumination correction to catalogue

Outputs:

- Single exposure images that corrected for linearity, dark current, flat field, stripes, sky, image persistence and crosstalk. A full WCS will appear in the header (SIMPLE_IMAGE)
- Illumination correction table (ILLCOR_TAB)

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	105 of 145

- Interleaved super-frame images from the above if microstepping has been done as part of the observing sequence. (INTERLEAVED_IMAGE)
- Stacked jitter images from the super-frames. Full WCS and photometric zero point will appear in the FITS header. (JITTERED_IMAGE)
- Associated confidence maps for each of the above output images. (CONFIDENCE_MAP)
- Object catalogue in the form of a FITS table if the **savecat** parameter has been set (OBJECT_CATALOGUE)

QC1 Parameters:

FRINGE RATIO SATURATION MEAN SKY SKY NOISE NOISE OBJ IMAGE SIZE APERTURE CORR ELLIPTICITY MAGZPT MAGZERR MAGNZPT LIMITING MAG ILLUMCOR RMS WCS DCRVAL1 WCS DCRVAL2 WCS DTHETA WCS SCALE WCS SHEAR WCS RMS ZPT 2MASS ZPT STDS

VIRCAM Functions Used:

vircam_darkcor, vircam_lincor, vircam_flatcor, vircam_defringe, vircam_persist, vircam_matchxy, vircam_crosstalk, vircam_imcore, vircam_getstds, vircam_platesol, vircam_matchstds, vircam_imdither, vircam_photcal, vircam_illum

Fatal Error Conditions:

- Null input frameset
- Input frameset headers incorrect meaning that RAW and CALIB frames cannot be distinguished
- No science frames in input frameset
- Missing master calibration frames or unreadable extensions in input frameset
- Inability to save output products
- **Non-fatal Error Conditions:**

None

Conditions Leading To Dummy Products:

8 Validation tests

Validation procedures will be developed for each function defined in chapter 6 and every recipe defined in chapter 7. In the case of the latter data described later in this chapter will be used to validate results. In the case of the former, recipe plugins have been written to test each function individually. What appears in this chapter is the set of test recipes as they currently stand, rather than the complete planned set. As these recipes may prove useful in themselves, these will be installed in the same tree as the reduction recipes. A very brief discussion of each test recipe is included in the next sections. As in previous recipe descriptions, each recipe has a parameter **ext** which is used to tell the recipe which of the FITS extensions you want to process. This parameter has been left of the parameter list for each recipe for the sake of brevity. The final section describes the test data that will be provided.

8.1 vircam_darkcor

Name:

vircam_darkcor

Purpose:

Test the function **vircam_darkcor** (section 6.2) by subtracting a dark frame from an input science frame.

Input Data:

- A raw science frame (required, SCIENCE_IMAGE)
- Master dark frame of the same exposure parameters as above (required, MASTER_DARK)

Parameters:

float **darkscl**

The factor by which to scale the dark frame before subtracting.

8.2 vircam_defringe

Name:

vircam_defringe

Purpose:

Test the function **vircam_defringe** (section 6.3) iteratively fitting a fringe pattern and subtracting it out.

Input Data:

- A raw science frame (required, SCIENCE_IMAGE)
- A master fringe frame (required, MASTER_FRINGE)
- Master mask in the form of a confidence map or a bad pixel mask (optional, MASTER_CONF or MASTER_BPM)

Parameters:

int **nbsize**

The size of the smoothing cells used in the large scale background removal algorithm

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	108 of 145

8.3 vircam_destripe

Name:

vircam_destripe

Purpose:

Test the function **vircam_destripe** (section 6.4) by modelling the background stripes in an input image and subtracting it out.

Input Data:

- A raw science frame (required, SCIENCE_IMAGE)
- Master mask in the form of a confidence map or a bad pixel mask (optional, MASTER_CONF or MASTER_BPM)

Parameters:

None

8.4 vircam_flatcor

Name:

vircam_flatcor

Purpose:

Test the function **vircam_flatcor** (section 6.5) by dividing a flat field image into an input science frame.

Input Data:

- A science frame (required, SCIENCE_IMAGE). For best results, this should have been previously dark corrected.
- Master twilight flat frame (required, MASTER_TWILIGHT_FLAT)

Parameters:

None

8.5 vircam_getstds

Name:

vircam_getstds

Purpose:

Test the function **vircam_getstds** (section 6.7) by extracting standard stars from the 2MASS catalogue that should appear on an input image.

Input Data:

• A science frame (required, SCIENCE_IMAGE).

Parameters:

char *catpath

The full path to the 2MASS PSC FITS tables.

8.6 vircam_imcombine

Name:

vircam_imcombine

Purpose:

Test the function **vircam_imcombine** (section 6.9) by combining a list of input images into a single output image.

Input Data:

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Ziorar y 2 oorgi	Date:	2006-12-12
System		Page:	109 of 145

• A list of science frames (required, SCIENCE_IMAGE).

Parameters:

int comb

Determines the type of combination that is done to form the output map. Can take the following values

- 1. The output pixels are medians of the input pixels
- 2. The output pixels are means of the input pixels

int scale

Determines how the input data are scaled or offset before they are combined. Can take the following values:

- 0. No scaling or biasing
- 1. All input frames are biased additively to bring their backgrounds to a common median level.
- 2. All input frames are biased multiplicatively to bring their backgrounds to a common median level.
- 3. All input frames are scaled to a uniform exposure time and then additively corrected to bring their backgrounds to a common median level.

int **xrej**

If set, then an extra rejection cycle will be run.

int **thr**

The rejection threshold in numbers of background sigmas.

8.7 vircam_imcore

Name:

vircam_imcore

Purpose:

Test the function **vircam_imcore** (section 6.10) by extracting objects from a science frame and writing them to a FITS table.

Input Data:

- A science frame (required, SCIENCE_IMAGE).
- An appropriate confidence map (required, CONFIDENCE_MAP or MASTER_CONF)

Parameters:

int **ipix**

The minimum size of an object in pixels in order for that object not to be considered spurious.

float **thr**

The detection threshold measured in units of the mean background noise

int icrowd

If set, then the function will attempt to de-blend merged objects float **rcore**

The core radius in pixels for the default profile fit.

int **nb**

The size in pixels of the grid squares used for background estimation. int **cattype**

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
	Liorary Doorgin	Date:	2006-12-12
System		Page:	110 of 145

The output catalogue type. This can be:

- 1. The 32 column INT Wide Field Camera format
- 2. The 80 column WFCAM format
- 3. A very minimal format which is just fine if all you want is positions
- 4. An object mask

NB: option 2 corresponds to the catalogues described in section 5.12.

8.8 vircam_imdither

Name:

vircam_imdither

Purpose:

Test the function **vircam_imdither** (section 6.11) by dithering a list of input files and their associated confidence maps into a single output map

Input Data:

- A list of science frames (required, SCIENCE_IMAGE).
- A list of confidence maps (required, CONFIDENCE_MAP or MASTER_CONF)

Parameters:

None

8.9 vircam_interleave

Name:

vircam_interleave

Purpose:

Test the function **vircam_interleave** (section 6.12) by interleaving a set of input science frames

Input Data:

- A set of science frame (required, SCIENCE_IMAGE)
- An appropriate set of confidence maps (required, MASTER_CONF)

Parameters:

None

8.10 vircam_lincor

Name:

vircam_lincor

Purpose:

Test the function **vircam_lincor** (section 6.13) by linearising a science frame. **Input Data:**

- A science frame (required, SCIENCE_IMAGE). For best results, this should have been previously dark corrected and flat field.
- A channel table (required, CHANNEL_TABLE)

Parameters:

None

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	111 of 145

8.11 vircam_matchstds

Name:

vircam_matchstds

Purpose:

Test the function **vircam_matchstds** (section 6.14) by matching an object catalogue with a standards table.

Input Data:

- An object catalogue (required, OBJECT_CATALOGUE).
- An extracted standards catalogue (required, STANDARDS_TABLE)

Parameters:

None

8.12 vircam_matchxy

Name:

vircam_matchxy

Purpose:

Test the function **vircam_matchxy** (section 6.15) by matching two object catalogues and working out the Cartesian positional difference.

Input Data:

• Two object catalogues (required, OBJECT_CATALOGUE).

Parameters:

None

8.13 vircam_mkconf

Name:

vircam mkconf

Purpose:

Test the function **vircam_mkconf** (section 6.16) by creating a confidence map from a master flat and a master bad pixel mask.

Input Data:

- A master flat field (required, MASTER_TWILIGHT_FLAT).
- A master bad pixel mask or master confidence map (required, MASTER_BPM or MASTER_CONF)

Parameters:

None

8.14 vircam_platesol

Name:

vircam_platesol

Purpose:

Test the function **vircam_platesol** (section 6.19) by fitting a plate constant model to a matched standards catalogue.

Input Data:

• A science frame with an initial WCS (required, SCIENCE_IMAGE)

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	112 of 145

• A matched standards table of objects on the science frame (required, MATCHED_STANDARDS_TABLE).

Parameters:

int **nconst**

The number of plate constants to fit. This must be either 4 or 6.

int **shiftan**

If this is set, then the position of the tangent point will be moved to take poor telescope pointing into account.

8.15 Validation Test Data

Test data will be provided for all of these validation procedures. In some cases this will consist of laboratory test data using the real VISTA focal plane detectors. In others, data from other instruments, namely WFCAM will be made to look like VISTA data. Where nothing else is available, simulated data will be generated and wrapped to look like VISTA data files. In the table below we give a list of the test data files that will be available for use in the validation procedures. Each FITS file will contain data for all sixteen detectors. The 'rich_field' files will consist of observations of a medium rich stellar field, which can be used for many of the validation tests we require. The series will be a 5 point jitter series, where each jitter point is also a 4 point microstep sequence.

Included in the test suite will be files that can be used in comparison with output from the test procedures. These will be monitored to ensure that:

- the image data arrays and table columns all contain exactly the same data
- a selection of relevant FITS header keywords have been created and are consistent with the test output files.
- output QC1 parameters match the known values from the test suite.

A selection of SOF files will also be included to insure that the tests are always done using the same files. Below is a list of test data to be expected in the test data suite.

datafile	comment
bpm.fits	A bad pixel mask
chantab.fits	The channel table (5.2)
dark_after_richXX.fits	A series of dark frames taken after the last rich_fieldXX frame.
darkXX.fits	A list of dark frames with the same exposure time as rich_fieldXX
darkXX_exp.fits	A series of dark frames with exposure times the same as those for domeflatXX_raw.fits
domeflatXX.fits	A series of dome flat exposures done with a series of exposure times with constant illumination. These have been dark corrected.
domeflatXX_raw.fits	A series of dome flat exposures done with a series of exposure times with constant illumination. These have not been dark corrected.
fringe.fits	A mean fringe frame

Table 8-1 Description of test data files

In the tables below we give a list of each of the VIRCAM functions and plugins from chapters 6 and 7 and the input files required from the test data suite. The files in the column 'output test files' will be used in to test consistency of result with the output of each function or plugin.

function	input test files	output test files
vircam_crosstalk	rich_field01.fits	xtalk.fits

9 Development Plan

Following [AD1] the DRL development is summarised in Table 9-1. In keeping with the fact that VISTA will (initially) be a single-instrument telescope, and so will essentially have a single commissioning period (no COM2), milestone 5 is omitted in order to keep the numbering consistent with general VLT planning.

Act ID	Milestone	Timeline	Deliv. ID	Deliverables
M-02	FDR	-4w	DR2	This document
	PAE	-6m	-	Data Reduction Library
				prototype with some basic
				dome-flat capability; will test
				instrument simulation data-
				interface compatibility.
M-03	PAE	-4w	DR3	Data Reduction Library v0.1
				Including: all basic planned
				functionality such that
				laboratory data from the
				instrument may be pipelined.
M-04	COM1	-4w	DR4	Data Reduction Library v0.5
				Including: bug fixes found at
				PAE plus any new (previously
				unplanned) functionality
				required as a result of PAE
-				detector characterisation.
M-06	PAC	-4w	DR6	Data Reduction Library v1.0
				Including: more bug fixes and
				any refinements and additions
				to analysis required as a result
				of experience gained with real
				commissioning data.
M-09	SO1	+8w	DR11	Data Reduction Library v1.y
				Including: more of above, and
				feedback from early science
				users.
		+8w	DR11	Final version this document

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
	Library Design	Issue:	1.6pre6
Data Flow	Library Design	Date:	2006-12-12
System		Page:	119 of 145

Context: Type: Value Format: Unit: Comment Format: Description:	process double %f count/s/detector cosmic ray/spurion rate [count/s/detector]. average no. of pixels rejected during combination of dark frames, used to give an estimate of the rate of cosmic ray hits for each detector. This can later be compared with previous estimates and monitored.
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>QC DARKCURRENT header process double %f adu/sec average dark current on frame [adu/sec]. measured using the median of the pixel values, can later be compared similar darks for trends</pre>
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>QC FLATRMS header process double %f fraction RMS flatfield pixel sens per detector [fraction]. RMS is defined here as the Gaussian equivalent MAD ie. 1.48*median-of-absolute-deviation from unity after normalising by median level ie. measuring the RMS sensitivity variation. The RMS can later be compared with library values for troubleshooting problems. significantly with time.</pre>
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	QC FLATRATIO_MED header process double %f scalar Median new/library flat frame [scalar]. Measure the median of the ratio of a new mean flat frame and a library flat frame.
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	QC FLATRATIO_RMS header process double %f scalar RMS new/library flat frame [scalar]. Measure the RMS of the ratio of a new mean flat frame and a library flat frame.
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	QC GAIN_CORRECTION header process double %f scalar detector median flatfield/global median [scalar]. the ratio of median counts in a mean flat exposure for a given detector relative to the ensemble defines the internal gain correction for the detector These internal relative detector gain corrections should be stable with time.
Parameter Name: Class:	QC READNOISE header

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	120 of 145

Context: Type: Value Format: Unit: Comment Format: Description:	<pre>process double %f electron readnoise [electron]. measured from the noise properties of the difference in two consecutive dark frames, using a MAD estimator as above for robustness against spurions. The noise properties of each detector should remain stable so long as the electronics/micro-code have not been modified.</pre>
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	QC GAIN header process double %f e/ADU gain [e/ADU]. determined from pairs of darks and flatfields of the same exposure/integration time and illumination by comparing the measured noise properties with the expected photon noise contribution. The gain of each detector should remain stable so long as the electronics/micro-code have not been modified.
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>QC LINEARITY header process double %f percentage percentage average non-linearity [percentage]. derived from measured non-linearity curves for each detector interpolated to 10k counts (ADUs) level. Although all infrared systems are non-linear to some degree, the shape and scale of the linearity curve for each detector should remain constant. A single measure at 20k counts can be used to monitor this although the full linearity curves will need to be examined quarterly [TBC] to look for more subtle changes.</pre>
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>QC LINFITQUAL header process double %f RMS fractional error in linearity fit Derived by applying the linearity coefficients to the image data that were used to measure them. This is the RMS of the residuals of the linearised data normalised by the expected linear value</pre>
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>QC BAD_PIXEL_STAT header process double %f scalar fraction of bad pixels/detector [scalar]. determined from the statistics of the pixel distribution from the ratio of two flatfield sequences of significantly different average count levels. The fraction of bad pixels per detector (either hot or cold) should not change</pre>
Parameter Name:	QC WCS_DCRVAL1

Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	QC APERTURE_CORR header process double %f mag 2 arcsec [mag] diam aper the aperture flux correc flux falling outside the a curve-of-growth of a s	tion for stel aperture. D	lar images due to Determined using

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	123 of 145

Alternative simple measure of image profile properties, particularly the presence of extended PSF wings, as such monitors optical properties of system; also required for limiting magnitude computations.

Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>QC ELLIPTICITY header process double %f scalar mean stellar ellipticity [scalar]. the detected image intensity-weighted second moments will be used to compute the average ellipticity of suitable signal:to:noise stellar images. Shot-noise causes even perfectly circular stellar images to have non-zero ellipticity but more significant values are indicative of one of: optical, tracking and autoguiding, or detector hardware problems.</pre>
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	QC MAGZPT header process double %f mag Photometric zero point [mag]. A measure of the photometric zero point using an aperture of 1* the core radius.
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	QC MAGZERR header process double %f mag Photometric zero point error [mag]. A measure of the RMS photometric zero point error using an aperture of 1* the core radius.
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	QC MAGNZPT header process double %f Number of stars in zero point calc. The number of stars on this image used to calculate the photometric zeropoint.
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>QC ZPT_2MASS header process double %f mag lst-pass photometric zeropoint [mag]. the magnitude of a star that gives 1 detected ADU/s (or e-/s) for each detector, derived using 2MASS comparison stars for every science observation. This is a first pass zero-point to monitor gross changes in throughput. Extinction will vary over a night, but detector to detector variations are an indication of a fault.</pre>
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	QC ZPT_STDS header process double %f mag photometric zeropoint [mag]. the magnitude of a star that gives 1 detected ADU/s

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010
Data Flow	Library Design	Issue:	1.6pre6
		Date:	2006-12-12
System		Page:	124 of 145

	(or e-/s) for each detector, derived from observations of VISTA standard star fields. Combined with the trend in long-term system zero-point properties, the ensemble "average" zero-point directly monitors extinction variations (faults/mods in the system notwithstanding) The photometric zeropoints will undoutbedly vary (slowly) over time as a result of the cleaning of optical surfaces etc.
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>QC LIMITING_MAG header process double %f mag limiting mag ie. depth of exposure [mag]. estimate of 5-sigma limiting mag for stellar-like objects for each science observation, derived from QCs ZPT_2MASS, SKY_NOISE, APERTURE_CORR. Can later be compared with a target value to see if main survey requirements (ie. usually depth) are met.</pre>
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	QC PERSIST_DECAY header process double %f s mean exponential time decay constant [s]. the decay rate of the persistence of bright images on subsequent exposures will be modelled using an exponential decay function with time constant tau. Requires an exposure on a bright star field followed a series of darks.
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>QC PERSIST_ZERO header process double %f fractional persistence at T0 (extrapolated). determined from the persistence decay behaviour from exponential model fitting. Requires an exposure on a bright star field followed a series of darks (as above)</pre>
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>QC CROSS_TALK header process double %f scalar average values for cross-talk component matrix [scalar]. determined from presence of +ve or -ve ghost images on other channels/detectors using exposures in bright star fields. Potentially a fully populated 256x256 matrix but likely to be sparsely populated with a small number of non-zero values of band-diagonal form. This QC summary parameter is the average value of the modulus of the off-diagonal terms. Values for the cross-talk matrix should be very stable with time, hardware modifications notwithstanding.</pre>
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	QC FRINGE_RATIO header process double %f scalar [scalar] Ratio of sky noise before/after fringe fit A robust estimate of the background noise is done before the first fringe fitting pass.

	Once the last fringe fit is done a final background noise estimate is done. This parameter is the ratio of the value before fringe fitting to the final value after defringing.
Parameter Name:	QC ILLUMCOR_RMS
Class:	header
Context:	process
Type:	double
Value Format:	%f
Unit:	mag
Comment Format:	[mag] RMS in illumination correction
Description:	The RMS of the illumination correction over all of

the frame.

The above dictionary is illustrated as a FITS header extract as it will appear in the perdetector extension header:

HIERARCH ESO OC DID = 'ESO-VLT-DIC.VI	IRCAM OC ' / Data dictionar
HIERARCH ESO QC RESETMED = 0.000000	/ median reset level
HIERARCH ESO QC RESETRED = 0.000000	/ RMS noise in combined reset fra
HIERARCH ESO QC RESETDIFF_MED= 0.000000	/ Median new-library reset frame
HIERARCH ESO QC RESETDIFF_MED= 0.000000 HIERARCH ESO QC RESETDIFF_RMS= 0.000000	/ [adu] RMS new-library reset fra
HIERARCH ESO QC DARKMED = 0.000000	/ median dark counts
HIERARCH ESO QC DARKMED = 0.000000 HIERARCH ESO QC DARKRMS = 3.456000	/ RMS noise of combined dark fram
HIERARCH ESO QC DARKDIFF_MED = 0.000000	/ Median new-library dark frame [
HIERARCH ESO QC DARKDIFF_MED = 0.000000 HIERARCH ESO QC DARKDIFF_RMS = 0.000000	/ [adu] RMS new-library dark fram
HIERARCH ESO QC DARRDIFF_RMS = 0.000000 HIERARCH ESO QC PARTICLE_RATE= 20.500000	/ cosmic ray/spurion rate [count/
HIERARCH ESO QC PARTICLE_RATE = 20.500000 HIERARCH ESO QC DARKCURRENT = 200.000000	/ average dark current on frame [
HIERARCH ESO QC FLATRMS = 0.000000	/ RMS flatfield pixel sens per de
HIERARCH ESO QC FLATRATIO_MED= 0.000000	/ Median new/library flat frame [
HIERARCH ESO QC FLATRATIO_MED= 0.000000 HIERARCH ESO QC FLATRATIO_RMS= 0.000000	/ RMS new/library flat frame [sca
	/ detector median flatfield/globa
HIERARCH ESO QC GAIN_CORRECTION= 0.950000	
HIERARCH ESO QC READNOISE = 150.000000	/ readnoise [electron].
HIERARCH ESO QC GAIN = 1.600000	/ gain [e/ADU].
HIERARCH ESO QC LINEARITY = 0.030000	/ percentage average non-linearit
HIERARCH ESO QC LINFITQUAL = 0.000000	/ RMS fractional error in lineari
HIERARCH ESO QC BAD_PIXEL_STAT= 0.006000	/ fraction of bad pixels/detector
HIERARCH ESO QC WCS_DCRVAL1 = 5.555550e-04	/ actual WCS zero point X - raw h
HIERARCH ESO QC WCS_DCRVAL2 = -5.555500e-04	/ actual WCS zero point Y - raw h
HIERARCH ESO QC WCS_DTHETA = 1.000000e-02	/ actual WCS rotation PA - raw PA
HIERARCH ESO QC WCS_SCALE = 9.444400e-05	/ measured WCS plate scale per de
HIERARCH ESO QC WCS_SHEAR = 1.000000e-04	/ power of cross-terms in WCS sol
HIERARCH ESO QC WCS_RMS = 9.444400e-06	/ robust RMS of WCS solution for
HIERARCH ESO QC MEAN_SKY = 12345.120000	/ mean sky level [ADU].
HIERARCH ESO QC SKY_NOISE = 2000.000000	/ RMS sky noise [ADU].
HIERARCH ESO QC SATURATION = 65535.000000	/ saturation level of bright star
HIERARCH ESO QC NOISE_OBJ = 150	/ number of classified noise obje
HIERARCH ESO QC IMAGE_SIZE = 0.500000	/ mean stellar image FWHM [arcsec
HIERARCH ESO QC APERTURE_CORR= 0.456000	/ 2 arcsec [mag] diam aperture fl
HIERARCH ESO QC ELLIPTICITY = 0.021100	/ mean stellar ellipticity [scala
HIERARCH ESO QC MAGZPT = 0.000000	/ Photometric zero point [mag].
HIERARCH ESO QC MAGZERR = 0.000000	/ Photometric zero point error [m
HIERARCH ESO QC MAGNZPT = 0.000000	/ Number of stars in zero point c
HIERARCH ESO QC ZPT_2MASS = 26.500000	/ 1st-pass photometric zeropoint
HIERARCH ESO QC ZPT_STDS = 26.400000	/ photometric zeropoint [mag].
HIERARCH ESO QC LIMITING_MAG = 24.567000	/ limiting mag ie. depth of expos
HIERARCH ESO QC PERSIST_DECAY= 40.000000	/ mean exponential time decay con
HIERARCH ESO QC PERSIST_ZERO = 0.800000	/ fractional persistence at TO (e
HIERARCH ESO QC CROSS_TALK = 1.000000	/ average values for cross-talk c
HIERARCH ESO QC FRINGE_RATIO = 0.000000	/ [scalar] Ratio of sky noise bef
HIERARCH ESO QC ILLUMCOR_RMS = 0.000000	/ [mag] RMS in illumination corre

The following table references the QC parameters with the functions and recipes where they are generated:

QC PARAMETER	FUNCTION	RECIPE
APERTURE_CORR	imcore	jitter microstep process
—		standard_process
BAD PIXEL STAT		linearity_analyse
CROSS TALK		crosstalk analyse
DARDIFF MED		dark combine
DARKCURRENT		dark current
DARKDIFF RMS		dark combine
DARKMED		dark combine
DARKRMS		dark combine
ELLIPTICITY	imcore	jitter_microstep_process standard_process
FLATRATIO_MED		dome_flat_combine twilight_combine
FLATRATIO_RMS		dome_flat_combine twilight_combine
FLATRMS		dome_flat_combine twilight_combine
FRINGE_RATIO	defringe	jitter_microstep_process standard_process
GAIN		detector_noise
GAIN_CORRECTION		twilight_combine
ILLUMCOR_RMS	illum	mesostep_analyse
IMAGE SIZE	imcore	standard_process jitter_microstep_process
_		standard_process
LIMITING_MAG	photcal	jitter_microstep_process standard_process
LINEARITY		linearity_analyse
LINFITQUAL		linearity analyse
MAGNZPT	photcal	jitter_microstep_process standard process
MAGZERR	photcal	jitter_microstep_process standard process
MAGZPT	photcal	jitter_microstep_process standard process
MEAN_SKY	imcore	jitter_microstep_process standard process
NOISE_OBJ	imcore	jitter_microstep_process standard process
PARTICLE RATE		dark combine
PERSIST DECAY		persistence analyse

                DRS DID
Parameter Name:
Class:
                header
               PROCESS
Context:
Type:
                string
Value Format:
                %30s
Unit:
Comment Format: Data dictionary for VIRCAM DRS
Description:
                Name/version of ESO DID to which DRS
                keywords comply.
Parameter Name: DRS NDITCOR
Class:
                header
Context:
                PROCESS
Type:
                unknown
Value Format:
                %b
Unit:
Comment Format:
                Flag for NDIT correction
                If this is set, then the frame has been corrected to
Description:
                a value of NDIT=1.
Parameter Name: DRS DARKCOR
                header
Class:
Context:
                PROCESS
Type:
                string
Value Format:

Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	DRS XOFFDITHER header PROCESS double %f X-pixels to jitter input image The number of pixels in X by which to jitter
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>the current input image relative to the output grid. DRS YOFFDITHER header PROCESS double %f Y-pixels to jitter input image The number of pixels in Y by which to jitter the current input image relative to the</pre>
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	<pre>output grid. DRS PROVXXXX header PROCESS string %s Input file # A set of FITS keywords that lists the files that were combined to form this output file. This establishes the provenance of the output file.</pre>
Parameter Name:	DRS SKYLEVEL
Class:	header
Context:	PROCESS
Type:	double
Value Format:	%f
Unit:	ADU
Comment Format:	[ADU] Mean sky level
Description:	The mean sky level in the image
Parameter Name:	DRS SKYNOISE
Class:	header
Context:	PROCESS
Type:	double
Value Format:	%f
Unit:	ADU
Comment Format:	[ADU] Mean sky noise
Description:	The mean sky noise in the image
Parameter Name:	DRS STDCRMS
Class:	header
Context:	PROCESS
Type:	double
Value Format:	%f
Unit:	arcsec
Comment Format:	[arcsec] RMS of the WCS fit
Description:	The RMS of the WCS fit
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	DRS NUMBRMS header PROCESS integer %d no. of stars in WCS fit Number of stars in the WCS fit
Parameter Name:	DRS WCSRAOFF
Class:	header

VISTA	Data Reduction	Doc:	VIS-SPE-IOA-20000-0010

Context: Type: Value Format: Unit: Comment Format: Description:	PROCESS double %f arcsec [arcsec] diff in RA after proc. The equatorial coordinates of the central pixel of the image is calculated both before and after the plate solution is found. This is the difference in the RA (in arcseconds).
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	DRS WCSDECOFF header PROCESS double %f arcsec [arcsec] diff in DEC after proc. The equatorial coordinates of the central pixel of the image is calculated both before and after the plate solution is found. This is the difference in the DEC (in arcseconds).
Parameter Name:	DRS BACKMED
Class:	header
Context:	PROCESS
Type:	double
Value Format:	%f
Unit:	adu
Comment Format:	[adu] Background median value
Description:	The most recent estimate of the background
Parameter Name:	DRS CLASSIFD
Class:	header
Context:	PROCESS
Type:	integer
Value Format:	%d
Unit:	Catalogue has been classified.
Comment Format:	Set if the classification software has been run on
Description:	this catalogue.
Parameter Name:	DRS THRESHOL
Class:	header
Context:	PROCESS
Type:	double
Value Format:	%f
Unit:	adu
Comment Format:	[adu] Isophotal analysis threshold
Description:	Isophotal analysis used in object detection.
Parameter Name:	DRS MINPIX
Class:	header
Context:	PROCESS
Type:	integer
Value Format:	%d
Unit:	pixels
Comment Format:	[pixels] Minimum size for images
Description:	Minimum number of pixels for an object to cover
Parameter Name: Class: Context: Type: Value Format: Unit: Comment Format: Description:	DRS CROWDED header PROCESS integer %d Crowded field analysis flag If set, then the deblending software has been used
Parameter Name: Class: Context: Type:	to extract the objects in this catalogue. DRS RCORE header PROCESS double

Context:	PROCESS
Type:	integer
Value Format:	%d
Unit: Comment Format:	Number of stars used photometric coropoint cals (h)
Description:	Number of stars used photometric zeropoint calc.(h) The number of stars used to calculate the photometric
Deberiperon	zeropoint for all the images reduced together.
	• 5 5
Parameter Name:	DRS IMADUMMY
Class:	header
Context: Type:	PROCESS unknown
Value Format:	%b
Unit:	
Comment Format:	Flag for dummy image/table
Description:	If this is set, then the image/table contained in
	this particular HDU is a dummy product.
Parameter Name:	DRS FLATIN
Class:	header
Context:	PROCESS
Type:	string
Value Format: Unit:	%S
Comment Format:	flat field used
Description:	The name of the flat field frame that was
	used to create this confidence map
Parameter Name:	DRS BPMIN
Class:	header
Context:	PROCESS
Type:	string
Value Format:	%s
Unit: Comment Format:	had nivel man used
Description:	bad pixel map used The name of the bad pixel mask image that was
202011201011	used to create this confidence map
Parameter Name:	DRS PERMASK
Class: Context:	header PROCESS
Type:	string
Value Format:	%s
Unit:	
Comment Format:	persistence mask used
Description:	The name of the persistence mask image that was used to create this confidence map
	abou of offende onth confidence map
Parameter Name:	DRS XTCOR
Class:	header
Context: Type:	PROCESS string
Value Format:	%s
Unit:	
Comment Format:	Crosstalk matrix table
Description:	Name of the crosstalk matrix table used to process
	this image
Parameter Name:	DRS FRINGEI
Class:	header
Context:	PROCESS
Type: Value Format:	string %s
Unit:	60
Comment Format:	Fringe file of nth pass
Description:	The name of the fringe file used in the nth
	defringing pass
Parameter Name:	DRS FRNGSCi
Class:	header
Context:	PROCESS
Type:	double
Value Format:	%f
